Vol. 14, No. 1, February 2023

Published on 28 February 2023

Aims & Scope
Osong Public Health and Research Perspectives (PHRP) is the international bimonthly (published at the end of February, April, June, August, October, and December) journal founded in 2010 by the Korea Disease Control and Prevention Agency (KDCA). With the mission of the KDCA, to create a disease-free world, PHRP encourages sharing medical information and knowledge in the areas of public health.

PHRP publishes original articles, review articles, guidelines, data profiles (including cohort profiles), special articles, short communications, viewpoints, editorials, commentaries, and correspondence, and book reviews, with a focus on the following areas of expertise: emerging infectious diseases, vaccinology, zoonotic diseases, non-communicable diseases, intractable and rare diseases, and human genomics.

Abstracting and Indexing Services
A part of articles, metadata, or full text is available from CrossRef metadata (2010−), PubMed Central (2010−), PubMed (2010−), Scopus (2010−), Embase (2010−), EBSCO Host (2010−), Directory of Open Access Journals (2018−), Korea Citation Index (2011−), and Emerging Sources Citation Index (2020−).

Open Access
PHRP is an open access journal. All contents of the journal are available immediately upon publication without embargo period (https://ophrp.org). All articles are distributed under the terms of the Creative Commons Attribution Non-Commercial License (http://creativecommons.org/licenses/by-nc/4.0/) which permits unrestricted non-commercial use, distribution, and reproduction in any medium, provided the original work is properly cited.

How we will reach a safer community

Jong-Koo Lee
National Academy of Medicine of Korea, Seoul, Korea

At the end of last year, the Republic of Korea, China, and Japan responded to concerns about the increase in new coronavirus disease 2019 (COVID-19) patients and the emergence of new variants by strengthening their surveillance and quarantine measures. However, contrary to these concerns, the number of new cases and deaths decreased globally, and some have expressed the opinion that the World Health Organization (WHO) should reevaluate the declaration of a global public health crisis. However, the decision has been made to maintain the crisis status for the time being [1]. Nevertheless, in the first week of January, when the Rt value dropped below 1, the Republic of Korea implemented an exit strategy and has enforced it since January 30 [2]. The use of masks in public health facilities where a large number of people gather is now at individuals’ discretion, while their use is mandatory in public transportation. And, it is necessary to transition to a long-term strategy based on the endemicity of COVID-19.

In the United States, the BXX.1.5 variant has become predominant, but it is expected to be resolved by May 11th [3]. Therefore, the search for an exit strategy should consider which measures should be prioritized to prepare for the next pandemic.

Building public trust in the safety and efficacy of currently available COVID-19 vaccines is of the utmost importance. Nationwide vaccination and booster programs have been initiated to curb the ongoing pandemic. During the vaccination campaign over the past 3 years, reports of vaccine adverse events have led to the need for research on the epidemiological relationship between vaccination and serious illnesses. To ensure scientific and objective judgments regarding this issue, the government has entrusted research on the adverse effects of COVID-19 vaccinations to the National Academy of Medicine of Korea. The study by Jeong et al. [4] published in this issue summarizes the methods used to research important adverse events following immunization; the ultimate goal of this research program is to increase the reliability of vaccines and combat vaccine hesitancy among medical professionals and the public.

The second measure that must be prioritized is the improvement of governance by amending laws and regulations related to infectious diseases. After the Middle East respiratory syndrome outbreak in 2015, the government introduced a legal system that classifies reporting and quarantine methods for disease management based on the severity of each disease group. However, the severity of COVID-19 can change depending on vaccination or mutations in the virus. Thus, the government has changed the classification of COVID-19 from a level 1 disease, which requires immediate reporting, isolation, and treatment cost support, to a level 4 disease, which requires self-payment of treatment and surveillance. This adjustment of the severity level has created confusion in its management and procedural problems related to changing legal measures. Therefore, the disease grouping according to management strategies should...
be discarded; instead, diseases should simply be listed in ‘Korean alphabetical’ reduce the confusion in the law, with lower-level laws such as presidential decrees and Ministry of Health and Welfare regulations governing the definition, diagnosis and treatment, public health measures, reporting methods, and international measures for each disease. An advantage of this approach would be that diseases requiring restrictions of individual freedom and rights would be strictly regulated by higher-level laws under the supervision of the National Assembly. This would ensure the ongoing stability of legal operations. In addition, delegating the details of disease management strategies to lower-level laws would allow more flexible management options depending on the epidemiological situation of each disease.

However, when amending laws and regulations, trends in international infectious disease management reform must be considered. The WHO recently announced a proposed revision of the International Health Regulations (IHR) and is currently seeking opinions [5]. The previous IHR focused on prevention and response in the public health sector based on traffic and trade following the international spread of diseases, whereas the recently proposed revision expands the scope of risks and emphasizes expanding the management of preparedness and social resilience in the healthcare system, as well as international cooperation and responsibilities. The government is also currently negotiating the Pandemic Prevention Treaty [6], which aims to overcome catastrophic infectious diseases through transparently communicating information about disease occurrence, strengthening the binding force of international law, ensuring equity in access to vaccines and treatments, easing the use of intellectual property rights, preparing the healthcare systems of low- and middle-income countries, addressing human rights issues related to discrimination and coercion, and addressing issues related to animals, humans, the environment, and health (One Health).

It is difficult to address pandemic diseases solely with the current legal system for infectious disease prevention and management. In other words, for managing all disaster-prone diseases, a new legal system that includes prevention, management, and collateral damage. In order to minimize the occurrence of cluster cases patients related to animals, humans, the environment, and health (One Health).

In the beginning of the COVID-19 pandemic, public health measures such as isolation and contact tracing were effective in blocking its transmission and reducing the number of patients. However, as local community transmission without epidemiological associations progressed, the severity of the disease decreased, and the vaccine uptake rate increased, infection prevention and management were abandoned altogether. The trade-off between preventing economic stagnation, achieving a high vaccination rate, and maintaining public health policies has been difficult, but well executed [8]. Nonetheless, the Republic of Korea has seen a globally unprecedented number of new cases. Therefore, ongoing efforts are needed to follow the principles of infection prevention and management even in a surge situation, in order to minimize the occurrence of cluster cases patients and collateral damage.

It is now increasingly believed that the COVID-19 pandemic will soon end; therefore, related budgets and programs are gradually decreasing, which raises concerns that programs may be terminated before the disease is eradicated [9]. We need to create alternatives to avoid making these concerns a reality, such as establishing a self-sufficient healthcare system at the district or regional level that can withstand surges, including tracing and quarantine for close contacts of infected patients at the local level, epidemiological investigations of cluster outbreaks, home-based medical care, primary care, the management of high-risk groups.
and critically ill patients, comprehensive medical care delivery systems, linkage between patient and public health information, collaboration between public health and private laboratories, government call centers, and social care. A comprehensive payment system, such as bundled payment or, capitation, needs to be created to make such a system work, in other words the health insurance payment system needs to be changed. A new model for district health systems should be developed to establish a collaborative system between the public health programs of health centers, metropolitan governments, and the central government and private medical institutions to prevent and treat various diseases. Pilot projects are needed to create this system, taking into account cases of establishing self-sufficient district healthcare systems through cooperation between the public and private sectors, such as the Accountable Care Organization model in the United States and the primary care network in Australia.

Finally, rapid diagnosis, treatment, as well as the scaling-up and roll-out of vaccines, are crucial for preparedness against diseases that pose public health crises. Latecomers to vaccine development have failed to dominate the market. In the future, mRNA vaccines can be used not only for preventing infectious diseases, such as malaria and measles, but also as therapeutic vaccines for chronic diseases; therefore, the market for them will continue to grow. However, although vaccines are a global public good, countries have had to pay significant costs to pharmaceutical companies to obtain additional vaccines beyond their allocated amounts in order to protect their own populations during this pandemic. As a result, low-income countries have failed to obtain enough vaccines to protect their citizens. While Moderna and Pfizer in the United States devoted all their resources to vaccine development and succeeded at “warp” or “light” speed, many countries with insufficient technology, human resources, and production capacity had to rely on imports and global aid, making it difficult to develop alternatives. They will face the same difficulties in the event of a new pandemic (Disease X). The news that the WHO is building regional spoke-hub centers [10] to solve these problems is undoubtedly welcome. Despite the creation of tools such as the COVAX facility, which is one of collaborative initiative between international organizations to respond to COVID-19, access to infectious disease management strategies such as PPE, diagnostics, therapeutics, and vaccines was difficult due to export controls. The importance of research and development cannot be overemphasized. At this point, we must confirm where our country stands in terms of developing and securing strategic resources for the next pandemic and prepare countermeasure. Concrete strategies are being discussed, such as governance reform for inter-ministerial collaboration and coordination, rapid research and development and scaling-up of vaccine production against circulating variants, the revision of regulations related to approval for emergency use, securing budgets for bio-related research and development and market formation, nurturing and developing related human resources, and improving incentives and entry barriers to promote corporate participation. However, there remains a significant gap in the world market for vaccine and therapeutic development.

ABSTRACT

With the introduction of coronavirus disease 2019 (COVID-19) vaccines, the Korea Disease Control and Prevention Agency (KDCA) commissioned the National Academy of Medicine of Korea to gather experts to independently assess post-vaccination adverse events. Accordingly, the COVID-19 Vaccine Safety Research Committee (CoVaSC) was launched in November 2021 to perform safety studies and establish evidence for policy guidance. The CoVaSC established 3 committees for epidemiology, clinical research, and communication. The CoVaSC mainly utilizes pseudonymized data linking KDCA’s COVID-19 vaccination data and the National Health Insurance Service’s claims data. The CoVaSC’s 5-step research process involves defining the target diseases and organizing ad-hoc committees, developing research protocols, performing analyses, assessing causal relationships, and announcing research findings and utilizing them to guide compensation policies. As of 2022, the CoVaSC completed this research process for 15 adverse events. The CoVaSC launched the COVID-19 Vaccine Safety Research Center in September 2022 and has been reorganized into 4 divisions to promote research including international collaborative studies, long-/short-term follow-up studies, and education programs. Through these enhancements, the CoVaSC will continue to swiftly provide scientific evidence for COVID-19 vaccine research and compensation and may serve as a model for preparing for future epidemics of new diseases.

Introduction

With the protracted coronavirus disease 2019 (COVID-19) crisis that began in December 2019, vaccines were hailed as a key to emerging from the pandemic and returning to normalcy. Through enormous efforts, vaccines were developed and approved in record time and quickly rolled out to the global population. However, the unprecedented speed of development and emergency use authorization, as well as the fact that some of the newly developed COVID-19 vaccines were based on innovative and unfamiliar platforms, raised safety concerns among experts and the general public. In Korea, COVID-19 vaccines were first introduced in late February 2021. Currently, Korea has one of the highest vaccination rates in the world, with 87.1% of the entire population being fully vaccinated (as of November 18, 2022).

Korea carries out vaccine safety monitoring through passive and active surveillance. For passive surveillance, safety data based on vaccine adverse events (AEs) reported by healthcare professionals, vaccinated individuals, and vaccine manufacturers are collected and analyzed, whereas active surveillance utilizes big data such as the vaccination registry, health insurance claims, and electronic medical records (EMRs) to proactively investigate selected population groups for the pre-emptive monitoring of AE cases [1,2].

In the United States (US), the Vaccine Adverse Event Report System serves as a passive vaccine surveillance system that is jointly operated by the Centers for Disease Control and Prevention (CDC) and the Food and Drug Administration (FDA) [3]. For active surveillance, V-Safe, a mobile phone-based system that collects individual AE reports, is operated by the CDC [4]. Once cases are collected, an EMR-based monitoring system called Vaccine Safety Datalink enables each participating site to prepare computerized data files by utilizing a standardized data dictionary for active monitoring [5,6]. The US FDA also established an active surveillance system called the Biologics Effectiveness and Safety System under the umbrella of the Center for Biologics Evaluation and Research. The FDA has used large-scale health insurance claims data and electronic health records to build a protocol for assessing the safety and effectiveness of COVID-19 vaccines [7,8].

The European Medicines Agency has a passive surveillance system called EudraVigilance [9], which collects and analyzes individual cases of suspected AEs after vaccination. For active surveillance, it relies on the Vaccine Monitoring Collaboration for Europe (VAC4EU) [10]. The United Kingdom operates its own existing program, called the Yellow Card Scheme, to collect suspected AEs in relation to drugs, vaccines, and medical devices. For COVID-19 vaccine monitoring, they have added the Coronavirus Yellow Card, a dedicated system for reporting only COVID-19–related vaccine side effects [11,12].

In Korea, since the rollout of the COVID-19 vaccine program, the Korea Disease Control and Prevention Agency (KDCA) has classified AEs into non-serious and serious cases for analysis based on patients’ status at the time of reporting. The results are disclosed on its website every week. In addition, Korea operates the national COVID-19 Vaccine Injury Compensation System for AEs that occur after vaccination. While reviewing requests for compensation, the KDCA saw a growing need to establish safety evidence, focusing on the domestic population. As the demand to generate evidence for vaccine surveillance intensified, the KDCA commissioned the National Academy of Medicine of Korea (NAMOK) to gather experts from medical, pharmaceutical, and healthcare sectors and independently assess the relationship between AEs and COVID-19 vaccines. As a result, the COVID-19 Vaccine Safety Research Committee (CoVaSC) was launched on November 12, 2021 to perform a wide range of COVID-19 vaccine safety studies assessing the relationship between AEs and vaccines in order to establish evidence for policy guidance.

Against the backdrop, this paper intends to provide a brief explanation of the CoVaSC, including its organizational structure, activities, major research processes, and findings.

Materials and Methods

Establishment of Committees

Under the leadership of committee president and assistant administrator, the CoVaSC established 3 committees for epidemiology, clinical research, and communication, as well as 13 sub-committees (Figure 1). The Epidemiology Committee uses COVID-19 vaccine AE reports to monitor and detect safety signals. It also utilizes linked KDCA–National Health Insurance Service (NHIS) data to establish research plans, conduct statistical analyses of the association between COVID-19 vaccines and AEs, and perform observed-to-expected ratio analysis for each target disease. The Clinical Research Committee is in charge of developing operational definitions, creating research protocols together with the Epidemiology Committee, and conducting literature reviews on target diseases and causality assessments based on the results of relationship analyses. The Clinical Research Committee has brought clinical experts on board to form ad-hoc committees for diverse diseases and take the lead in research activities. The Communication Committee develops strategies for communication with healthcare professionals and the public. It also creates press releases and organizes forums to release CoVaSC research findings. A total of 22 members have contributed to CoVaSC research, together
with 159 experts in advisory groups.

**Scopes and Topics of Research**
The CoVaSC has a broad set of roles, including basic surveys, research plan development, data analysis, and reporting (Figure 2). To ensure the transparent sharing of research outcomes with healthcare professionals and the general public, it organizes forums and briefings. The major contents of CoVaSC research include (1) domestic and international trends in causality assessment and the results of literature reviews, (2) monitoring of AE reports and signal detection, (3) statistical analysis of domestic data related to COVID-19 vaccines, (4) causality assessment between COVID-19 vaccination and AEs, and (5) communication with healthcare professionals and the public through regular forums. Promoting close cooperation with the KDCA and NHIS is crucial for the success of CoVaSC research since those 2 organizations are major resources for research data. The KDCA, for example, provides access to its vaccination database, which encompasses healthcare personnel’s reports on AEs in relation to COVID-19 vaccines and COVID-19 vaccination records of the entire population in Korea. The NHIS has an enormous database of health insurance claims, which are generated when healthcare facilities claim insurance reimbursements for medical services that they provide to patients, which covers the entire Korean population of about 51 million. The NHIS links its database with that of the KDCA and provides a data analysis room for researchers to use. The CoVaSC, KDCA, and NHIS hold regular monthly meetings to share their research findings and foster collaboration.

**Sources of Research Data**

**KDCA vaccination data and AE reports**
Since the launch of the COVID-19 vaccine program in Korea on February 26, 2021, the KDCA has collected vaccination...
data from the entire population, and details of adverse reactions have been reported by healthcare clinics and medical institutions in accordance with the Infectious Disease Control and Prevention Act. In addition, in June 2000, Korea started to register immunization records electronically under the National Immunization Program (NIP), and since 2002, all the immunization records at local healthcare centers and private clinics have been kept in the KDCA’s electronic system [13]. The records of COVID-19 vaccines are managed separately from the NIP, and various information, including the vaccination date, vaccine dose, and type of vaccine, is electronically stored. Regarding AE reports, information on the types of AEs, date of onset, and diagnosis and prognosis are collected. These data enable potential safety signals to be detected early and cost-efficiently through AE monitoring.

NHIS claims data
Since Korea has a health insurance system with universal coverage, all medical services provided to the public are linked with insurance claims data. After providing medical services, healthcare institutions make claims for service fees to the NHIS (the insurer), and insurance claims data are generated in the process. As NHIS manages enrolled and insured individuals and pays costs based on the billing records, its database has accumulated a vast array of data, including insurance eligibility, medical services and prescription records, details of health screening, and information on healthcare institutions [14]. The NHIS claims database provides information on the medical services that have been offered due to AEs after COVID-19 vaccination.

The CoVaSC received pseudonymized data that connected KDCA’s COVID-19 vaccination data and NHIS’s database. The CoVaSC researchers could access the database to perform
analyses at NHIS’s data analysis center. The data were periodically updated during the research period to keep abreast with the latest trends.

Research Process

Figure 3 shows a general overview of CoVaSC’s research process.

Defining target diseases and forming an ad-hoc committee for each disease

In consultation with the KDCA, the CoVaSC first created a list of adverse events of special interest (AESIs), for which safety issues have been raised in relation to COVID-19 vaccines. In order to set priorities for causality analysis, the CoVaSC conducted a survey in December 2021 to weigh epidemiological and clinical significance and public interest among different research candidates. For hematologic disorders, the incidence rate per 100,000 was first calculated for each disease to identify disorders with an observed occurrence that is significantly higher than expected. Table 1 shows the final priority list of diseases for causality assessment.

After defining the target diseases, an ad-hoc committee was established for each target disease, which comprised clinical and epidemiological specialists in the target disease. After finalizing the target diseases, a kick-off meeting of each relevant ad-hoc committee was held to discuss research plans for causality evaluation between the vaccine and the target disease.

Developing study protocols

Prior to the official start of the research, protocols were written, revised, and reviewed for each target disease. These research protocols described the purpose, duration, and subjects of research, exposure information, the operational definition of the target disease, study design, and statistical analysis methods. Clinicians from each ad-hoc committee devised an operational definition of the related disease by applying diagnosis codes based on the International Classification of Diseases, 10th Revision, procedure/surgery codes, and criteria to exclude underlying diseases. The protocols were first drafted by epidemiologists and then reviewed by the clinicians in the relevant ad-hoc committees for revision and finalization.

Performing data analysis

Since the CoVaSC relies on a huge amount of data, such as COVID-19 vaccination records, insurance claims data, and AE reports of the entire Korean population, all the missing values and outliers have to be dealt with to extract clean data for the analysis dataset. For example, there were cases where 1 of the 2 vaccination records was missing for fully vaccinated people, or the same vaccination was recorded redundantly, which should have been excluded. Once the data mining process was completed, demographics and vaccination status were reviewed for a technical analysis, and the associations between AEs and COVID-19 vaccines were investigated.

---

**Step 1** Define target diseases and establish ad-hoc committees

- Based on the pre-defined list of AESIs, select priority disease targets
- Establish ad-hoc committee to seek clinical advice for target AEs

**Step 2** Develop research protocols

- Create research protocols based on the consultation between Epidemiology Committee and the corresponding ad-hoc committee
- Establish operational definition of target disease
  - Diagnosis code, surgery/procedure code, disease history

**Step 3** Perform data analysis

- Utilize KDCA’s COVID-19 vaccination data+NHIS’s health insurance claims data
- Produce clean data for analysis dataset
  - Deal with missing values and outliers
- Conduct technical analysis and analyze associations with COVID-19 vaccines

**Step 4** Perform causality assessment

- Compile research findings to produce reports with figures and tables
- Perform causality assessment based on relevant criteria
- Review and conclude research results

**Step 5** Announce research findings

- Share research findings through press releases and public forums
- Hold forums online and broadcast through YouTube to reach out to the general public

---

Discussing study results and assessing causal relationships
After analyses were completed, study reports were created, including tables and figures to reveal any associations that were found. To perform causality assessments between COVID-19 vaccines and AEs, CoVaSC referred to the Committee of US Surgeon General Criteria [15] and the Bradford-Hill Criteria [16], the 2 globally recognized criteria for causality investigations. The ad-hoc committee of the relevant disease then compiled the analysis results, as well as evidence from Korea and abroad, for a comprehensive review. After a discussion among the ad-hoc committee members, the final decision was made on whether the case fulfilled the causality criteria.

Announcing research findings
The CoVaSC created press releases and held forums to share its research outcomes with healthcare professionals and the general public. Epidemiologists on the Epidemiology Committee announced the results of epidemiological studies, and clinicians on the Clinical Research Committee shared the results of causality assessments. The CoVaSC held 4 forums by the end of 2022. The first forum briefly explained the purpose and methodology of its research, and the other 3 were held to share research findings. The first forum was held on November 26, 2021 to introduce the CoVaSC, its methodology for epidemiological research, and the criteria that would be used for causality assessment. During the second forum on March 4, 2022, the results of safety monitoring and causality assessments between COVID-19 vaccination and AEs were announced, focusing on death, myocarditis/pericarditis, acute myocardial infarction, and stroke. In the subsequent third forum on May 12, the study findings regarding Guillain-Barré Syndrome, Miller-Fisher Syndrome, heart failure, aortic dissection, acute transverse myelitis (ATM), and acute disseminated encephalomyelitis were released. The fourth and final forum on August 11 showed the results of causality assessments for thrombosis-related diseases, such as deep vein thrombosis, cerebral venous sinus thrombosis and abnormal uterine bleeding (AUB), and presented the causality assessment guidelines for COVID-19 vaccine safety studies. The forums were conducted online and broadcast through YouTube to reach the broader public.

Major Research Methodologies
Detecting signals from AE reports
To detect signals of vaccine-related adverse reactions based on the monitoring of AE reports, the research used 2 well-known disproportionality analysis indices for data mining: (1) the proportional reporting ratio (PRR) and (2) reporting odds ratio (ROR). The PRR is calculated by dividing the percentage of a specific AE of a specific COVID-19 vaccine versus the percentage of the same AE from a different COVID-19 vaccine, whereas the ROR is calculated by dividing the odds of AE caused by a specific COVID-19 vaccine by the odds of AE from a different vaccine. Using these 2 indices, the committee explored different combinations of vaccines and AEs to identify adverse reactions that were more frequent than the pre-defined values. Then they observed them as signals to identify statistical associations between a particular AE and a particular COVID-19 vaccine.

Observed-to-expected ratio analysis

For the diseases selected for the association analysis, an observed-to-expected ratio analysis was performed that referred to the pre-COVID occurrence rate to predict the expected occurrence rate after the vaccination against COVID-19. On this basis, the difference between the expected and the observed incidence rates was evaluated. For this study, the monthly incidence rate of each target disease was calculated for 10 years before the COVID-19 vaccination program. The prediction model was produced based on the observed incidence rate using an auto-regressive integrated moving average (ARIMA) model. A seasonal ARIMA model was applied in order to reflect changes in demographics and medical behaviors over time. If the observed value deviated beyond the 95% confidence interval of the predicted value, Poisson regression was conducted.

Cohort study

A cohort study was designed to compare the incidence rate of relevant AEs between the groups with and without vaccine exposure. The incidence rate and the relative and absolute risk rates of relevant AEs were assessed within the follow-up period in the exposed and the non-exposed groups. Although selecting the most appropriate comparator is critically important for cohort studies, it was a herculean task to define the non-exposure group for COVID-19 vaccines due to the overwhelmingly high vaccination rate. Therefore, the research used people who had received influenza shots, for example, as an active control group or people with the same demographic profile and comorbidity index score as a historical control group to analyze outcome variables, particularly death.

Self-controlled study

If the process of selecting subjects is likely to trigger high selection bias, a self-controlled study design can be applied, which sets an individual patient as a control against himself or herself to address time-invariant confounders. In vaccine safety research, self-controlled case series (SCCS) and self-controlled risk interval (SCRI) designs are mainly used as self-controlled studies. An SCCS is an epidemiological study design that uses patients who experienced the outcome variables during the observation period to specify the risk window during which each individual is potentially at a higher risk of developing AEs. The remaining non-risk period is set as the control window to compare the AE incidence rate between the risk window and the control window [17,18], whereas an SCRI investigates people who have been vaccinated to compare the AE incidence rate between the pre-defined risk period and the control period before or after vaccination [19]. A major difference between the 2 research designs is that an SCCS defines research subjects based on the occurrence of the outcome variables. After specifying the risk window, it defines the rest of the entire research period as the control window. However, an SCRI analyzes people who have been vaccinated and sets a certain period as the control window; therefore, the observation span of an SCRI is shorter than that of an SCCS.

Results

The CoVaSC analyzed the association of AEs likely to occur after COVID-19 vaccination based on the monitoring of AE reports. For AE report monitoring, the committee studied various subgroups defined according to age, sex, and vaccine to describe the status and trend of reporting. It also explored AE signals for different types of COVID-19 vaccines. The CoVaSC conducted diverse analyses on 15 different AEs to estimate their relationship with COVID-19 vaccines (Table 2).

Among the diseases where statistical associations were found, myocarditis, pericarditis, and AUB furnished evidence to guide policies. On March 4, 2022, myocarditis was announced to have an association with COVID-19 vaccines. Accordingly, the COVID-19 Vaccine Injury Compensation Committee acknowledged a causal relationship between myocarditis and the mRNA vaccine and applied the decision retroactively. This decision opened the door for those whose previous compensation requests were rejected on the ground of insufficient evidence to receive compensation with no strings attached. For pericarditis not accompanied by myocarditis, based on the finding released on May 12, 2022, the decision was reverted from “inadequate” to “adequate” evidence for its causality with COVID-19 vaccines. This decision also applied retroactively, but with the condition that those who had yet to apply for compensation should submit an application. As of August 16, 2022, AUB was added to the list of diseases with a suspected association (but with insufficient evidence for causality) after releasing relevant research results.

Discussion

Since Korea introduced the COVID-19 vaccination program without having a monitoring and surveillance system in place, the CoVaSC was established in 2021 to conduct scientific safety assessments of adverse reactions to COVID-19 vaccines based on the available domestic data. As such, the CoVaSC has carried out a diverse range of research, and its research findings have contributed to policy-making and scientific studies. Fifteen diseases were investigated for
their associations with COVID-19 vaccines. Victims of AEs for which the CoVaSC suggested potential causality received compensation, and some AEs were added to the list of diseases with a potential association with COVID-19 vaccines. However, due to the limitations of the available data at the time of the initial research, the analyses of some diseases, such as ATM and deep vein thrombosis, were postponed.

Various factors have enabled such large-scale, comprehensive research. First, databases played a significant role. The availability of population-wide data, including vaccination records and medical use data, provided a significant boost to the CoVaSC. The KDCA-NHIS linked data offered a rich source of information to conduct association studies. The data have been constantly updated to stay relevant and up-to-date, thanks to well-established governance and close collaboration between the KDCA and the NHIS.

Second, the participation of experts from various fields warrants mention. AESIs are very diverse, requiring input from clinical experts in various specialties along with experts in epidemiology, healthcare, and statistics. Therefore, the CoVaSC established Epidemiology, Clinical Research, and Communication Committees and efficiently assigned them different roles. In addition, professional advisory groups and ad-hoc committees for different target diseases were formed in order to ensure efficient and highly coordinated research. By assigning experts to the right place while promoting collaboration, the CoVaSC was able to produce solid research results in a relatively short period of time.

Still, there is room for improvement. It is undeniably true that AE reports, vaccination data, and health insurance claims data provide a valuable source of information, yet they have the potential to trigger bias. AE reports are about suspected, not confirmed cases; therefore, they must be linked with clinical data such as EMRs to cross-check whether the diagnosis is correct and appropriate. For insurance claims data, clinical experts devised operational definitions to estimate statistical associations, but often without a full understanding of the actual patients who experienced these conditions. For example, a large number of victims complaining of chest pain were diagnosed with pericarditis, but this diagnosis later turned out to be incorrect, which exaggerated the number of pericarditis occurrences and caused difficulty in accurately estimating the rate.

Furthermore, the process of submitting, reviewing, and paying out of health insurance claims caused a time lag in the data, which may compromise the accuracy of real-time analysis. In order to overcome these issues, the CoVaSC plans to develop methods of improving diagnostic accuracy, such as conducting EMR reviews for diseases with extremely low occurrence rates or with low diagnostic accuracy. In addition, for diseases with high clinical significance but low incidence, it plans to establish a network of hospitals to promote joint, collaborative research.

The CoVaSC launched COVID-19 Vaccine Safety Research Committee

Center in September 2022 and reshuffled the organization from the previous 3-committee system to a 4-division structure, which includes the following divisions: (1) Epidemiological Research, (2) Clinical Research, (3) Communication and Education, and (4) International Cooperation. Under these 4 divisions, there are 7 teams for epidemiological research, 7 teams for clinical research, 1 team each for communication and education, and 1 international cooperation team. Building on existing AE monitoring and causality assessment, the CoVaSC plans to carry out diverse research with the newly established COVID-19 Vaccine Safety Research Center, including international studies, long-/short-term follow-up studies, the construction of a nationwide hospital research network, and educational programs. In particular, with the enactment of the Public Notice on the Designation of the Assigned Agencies to Perform COVID-19 Vaccine Safety Researches & Investigations on November 4, 2022, the commissioner of the KDCA requested the NAMOK to engage in COVID-19 vaccine safety studies and surveillance research, which provides a solid foundation to operate the COVID-19 Vaccine Safety Research Center.

To further improvement of the causality assessment, the CoVaSC applied reports and frameworks from the National Academy of Medicine of the US. Based on this experience, it decided to use both epidemiological and mechanistic approaches for future studies to draw conclusions on the associations between AEs and COVID-19 vaccines. To promote international research, the CoVaSC has arranged several international conferences and webinars with the US CDC, the National Center for Immunization Research and Surveillance from Australia, and the World Health Organization to have concrete discussions on study designs and statistical analysis methods. Starting from its collaboration with the Global Vaccine Data Network, the CoVaSC has pursued broader opportunities to work together with other international institutions to perform joint research on the safety assessment of COVID-19 vaccines. In addition, for diseases difficult to analyze with insurance claims data (for instance, if a disease is not reimbursable or patients rarely visit hospitals for the disease), the CoVaSC plans to develop tools to conduct surveys for short- and long-term follow-up. It will also launch an educational training program for clinicians and the general public to deepen their understanding of terminology and causality assessment methodologies in order to lay the groundwork for effective communication to share research results in the future.

Conclusion

The CoVaSC will continue to serve as an organization that swiftly provides scientific evidence for COVID-19 vaccine surveillance. As time passes, its safety database and evidence will constitute essential sources of information to guide policies and help us tackle public healthcare crises in the future. The CoVaSC’s governance and research processes can also serve as a reference for future research projects.

ABSTRACT

Objectives: On February 16, 2022, 12 cases of hepatitis E virus (HEV) infection were reported in a food manufacturing factory in Korea. The aim of this study was to identify additional cases and to determine the source of this HEV outbreak.

Methods: This study was an in-depth investigation of 12 HEV immunoglobulin M (IgM)-positive cases and their demographic, clinical, and epidemiological characteristics. On-site specimens were collected from the environment and from humans, and a follow-up investigation was conducted 2 to 3 months after the outbreak.

Results: Among 80 production workers in the factory, 12 (15.0%) had acute HEV infection, all of whom were asymptomatic. The follow-up investigation showed that 3 cases were HEV IgM-positive, while 6 were HEV IgG-positive. HEV genes were not detected in the HEV IgM-positive specimens. HEV genes were not detected in the food products or environmental specimens collected on-site. HEV was presumed to be the causative pathogen. However, it could not be confirmed that the source of infection was common consumption inside the factory.

Conclusion: This was the first domestic case of an HEV infection outbreak in a food manufacturing factory in Korea. Our results provide information for the future control of outbreaks and for the preparation of measures to prevent domestic outbreaks of HEV infection.

Keywords: Asymptomatic infections; Diseases outbreaks; Hepatitis E; Korea
Introduction

Hepatitis E is an acute viral infection caused by the hepatitis E virus (HEV) [1]. According to the World Health Organization, 20 million cases of hepatitis E are reported annually, of which 3.3 million (16.5%) are symptomatic. In 2015, 44,000 people died from hepatitis E [2].

The incubation period of hepatitis E is 15 to 64 days (average, 40 days) [3]. Hepatitis E is a waterborne and foodborne disease orally transmitted through the consumption of contaminated water or food. The signs and symptoms include fever, fatigue, vomiting, stomachache, jaundice, and dark brown urine. Although these symptoms are like those of hepatitis A, most cases of hepatitis E are asymptomatic. Hepatitis E can progress to chronic infection in immunocompromised patients [1,4].

HEV has 8 genotypes, 4 (1–4) of which are reported in humans [5]. HEV genotypes 1 and 2 are mostly found in Asian and African countries with poor sanitation and are transmitted through the fecal-to-oral route, often in large-scale waterborne outbreaks. HEV genotypes 3 and 4 cause zoonotic infection between humans and animals, mainly boars, pigs, and deer. Sporadic cases of infection through the consumption of contaminated foods have been reported in Europe, North America, parts of Asia (Japan, Taiwan), Australia, and New Zealand [4,6]. HEV genotype 7 has been reported in people who consume meat and milk derived from camels [7].

Sporadic outbreaks of hepatitis E from the consumption of undercooked meat and processed meat products have been reported in the developed countries of Europe and Japan [4,8]. Domestic cases of hepatitis E have been reported from the consumption of boar bile and raw roe deer meat [9–11]. As a result, interest in hepatitis E has expanded, and hepatitis E was designated a class 2 notifiable infectious disease with commencement of a mandatory surveillance system on July 1, 2020. According to statistics on infectious diseases by the Korea Disease Control and Prevention Agency (KDCA), approximately 500 cases a year are reported. However, when compared to hepatitis A, B, and C, awareness of hepatitis E is relatively low among healthcare workers and the public in Korea. Studies on hepatitis E are lacking in Korea, which is a non-epidemic area of acute hepatitis E [12].

On February 16, 2022, an outbreak of hepatitis E was reported in a food manufacturing factory in Korea during a routine health examination of workers. As this was the first reported domestic outbreak of hepatitis E, the KDCA examined the incidence and cause of the outbreak in the factory and initiated an epidemiological investigation to establish preventive measures.

Materials and Methods

Study Background and Settings

The site of the outbreak was a food manufacturing factory that produced food by mixing, charging, drying, and packing. Among the 162 employees, 80 were production workers. The processing system in the factory was automated and all operations were sealed. There was no process in which employees had direct contact with the raw materials and products. The production workers worked in 3 shifts (day, evening, and night), and there was a cafeteria used by all employees in the factory. According to the requirements of importing countries, the production workers underwent annual health examinations with a surveillance checklist that included bacillary dysentery, hepatitis A, and hepatitis E. On February 16, 2022, the routine on-site health examination of 80 production workers showed 12 cases of hepatitis E infection.

Considering that the cases were clustered in one factory during a single time period, and that the number of cases was higher than the usual occurrence reported in the province where the factory was located (4 cases annually), we identified this cluster as an HEV outbreak within the factory.

Epidemiological Investigation

Case definition

According to the diagnostic criteria for hepatitis E, we defined cases as those who tested positive for HEV immunoglobulin M (IgM) among the production workers who worked and underwent routine health examinations in the factory from December 14, 2021 to February 16, 2022. As all cases were asymptomatic, diagnostic test results were substituted for symptoms.

Study design

The cases were detected through routine health examinations and not based on the manifestation of symptoms after consumption of a particular food item. Therefore, the source of common exposure was unclear. The long incubation period of acute hepatitis E (15–64 days) hindered the application of cohort or case-control studies. Therefore, a case series study was conducted involving the production workers who met the case definition.

Case investigation

Basic case information was obtained using an epidemiologic report form. An in-depth epidemiological investigation was conducted through phone calls. Demographic information
was collected including sex, age, and residence, as well as epidemiological characteristics including signs and symptoms; history of underlying disease; history of HEV infection; travel history; history of animal contact; history of contact with HEV-infected patients; history of blood donation, blood transfusion, or organ donation; and history of food consumption during the risk exposure period (15–64 days) and the incubation period for index patients (December 14, 2021 to February 1, 2022). Clinical characteristics were obtained, including HEV test results and alanine transaminase and aspartate transaminase measurements. The history of hospital visits during the estimated exposure period was obtained from the drug utilization review (DUR) data of the Health Insurance Review & Assessment Service. Record reviews were used, since all HEV-positive cases were reportedly asymptomatic.

Environmental Investigation

Investigation of the cafeteria and food items
Considering that more than 1 month had passed since the diagnosis of the cases, and that all the cases used the same cafeteria in the factory, the investigation focused more on the cafeteria and food items than on the worksite or environment. The Food Sanitation Act mandates the preservation of food for 144 hours after provision. Since the preserved foods from the risk exposure period were not available, the most recent preserved foods were collected.

The consumption history of meat and processed meat products from the list of food items provided at the cafeteria was analyzed in addition to the in-depth epidemiological investigation. The consumption history of raw meat, processed meat products, animal liver/intestine, and frozen fruits was examined. Furthermore, the kitchen and cooking environment, method of food preservation and distribution, and supply of food ingredients were investigated by interviewing kitchen employees. Since the IgM-positive HEV infection had occurred in the past, recent changes in suppliers of food ingredients, kitchen workers, and the cooking environment were also investigated.

Investigation of the worksite and environment
Environmental specimens were collected from workroom handles, manufactured products, and water that the cases could have been in contact with while working.

Laboratory Testing
Anti-HEV IgM was tested in the positive plasma samples using an abia HEV IgM enzyme linked immunosorbent assay kit (AB Diagnostic Systems GmbH) according to the manufacturer’s manual. Anti-HEV IgM-positive samples were tested for HEV RNA using the PowerChek HEV virus qRT-PCR kit (KogeneBiotech Co.). Primers and probes were designed based on multiple sequence alignment of the HEV genome sequences in the open reading frame 2/3 region. Environmental samples were taken from within the facility, and HEV RNA quantitative reverse transcription polymerase chain reaction (qRT-PCR) tests were performed. Environmental tests were conducted on water purifiers, doorknobs, telephones, manufactured products in the workplace, kitchen tools in the cafeteria, and preserved foods.

Follow-up Investigation
To monitor the onset of additional cases and determine the continuation of the outbreak, a follow-up was conducted in April 2022, 2 to 3 months after the outbreak was detected, by screening for HEV IgM, HEV IgG, and HEV genes.

Data Analysis
Descriptive statistics (presented as frequencies and percentages) were used to analyze differences in the demographic, clinical, and epidemiological characteristics of the cases collected during the epidemiological investigation. Microsoft Excel 2013 (Microsoft Corp.) was used for the analysis.

Ethics Approval
The study protocol was approved by the Institutional Review Board of the KDCA (IRB-2022-08-03-PE-A).

Results
Descriptive Epidemiology
On February 16, 2022, 12 of 80 production workers in the factory tested positive for HEV in their routine on-site health examinations.

Demographic and clinical characteristics showed that all 12 cases were men and the median age was 50 years (range, 43–59 years). The attack rate of acute hepatitis E among production workers was 15.0% (12/80). Regarding age, 18.2% of production workers (8/44) were in their 50s and 12.9% (4/31) were in their 40s. The attack rate according to work division was 23.5% (4/17) in department B and 18.8% (3/16) in department E (Table 1).

All cases were asymptomatic (HEV carriers), and most (10/12) showed normal liver function, based on alanine transaminase and aspartate transaminase levels. A history of chronic diseases (e.g., hypertension) was found in 8 cases, and cases no. 1, no. 3, and no. 8 tested anti-HEV IgM-positive since their previous health examination in 2020. Although all cases reported being asymptomatic during the investigation, the
DUR of the Health Insurance Review & Assessment Service revealed that 1 case (no. 8) had presented with digestive symptoms (i.e., gastroenteritis and colitis) during the estimated HEV exposure period (December 2021 to February 2022) (Table 2).

The analysis of the epidemiological characteristics of the production workers revealed that, within the estimated HEV exposure period, there was no history of overseas travel (including to acute hepatitis E epidemic regions), blood donation, blood transfusion, organ donation, or contact with a hepatitis E-infected patient. As zoonotic infection is possible in acute hepatitis E, any history of animal contact while hunting or while in a barn or farm near the factory or home was examined. The results showed that case no. 12 had a small barn containing 6 hens and 2 dogs. Any history of consuming undercooked meat, animal liver or bile, shellfish, processed meat products (e.g., unheated sausage), or frozen fruits was investigated. Cases no. 4 and no. 10 had consumed cow liver or raw meat but did not develop symptoms (Table 3).

Environmental Investigation
During the on-site epidemiological investigation, we collected and tested 3 human specimens from the kitchen employees; 19 environmental specimens from handles in the worksite, kitchen knives, cutting boards, washcloths, preserved food products, and water; and 4 specimens from manufactured products. However, no pathogens were isolated from these specimens, and the source of infection could not

be determined. The factory operated its own self-service cafeteria, and no specific problems were identified in the sanitary conditions of the cooking environment, the cooking staff, or the food suppliers. All processes within the workshop were automated and contained within a closed workspace. Therefore, there was no contact between the workers and the products, and the likelihood of contamination of the manufactured food by workers was assessed to be low.

Follow-up Investigation
The follow-up tests revealed 3 HEV IgM-positive results (3 previously HEV IgM-positive cases) and 6 HEV IgG-positive results (2 previously HEV IgM-positive cases and 4 previously negative cases). Viral genes were not isolated in the IgM-positive specimens (Table 4). Based on the results of the follow-up investigation, the 3 HEV IgM-positive workers were among those who had first been reported in February 2022, and no new cases had developed among the HEV IgM-negative workers.

Discussion
Hepatitis E infection was designated a class 2 notifiable infectious disease in July 2020 in Korea. According to the Health Insurance Review and Assessment Service, the annual number of reported cases of acute hepatitis E was fewer than 100 between 2010 and 2018. Reported cases reached a peak of 219 in 2019, dropped to 169 in 2020, then increased again to 235 in 2021.

Hepatitis E infection presents a wide range of clinical symptoms, from no or mild symptoms to fulminant hepatitis. Unlike previous reports outside Korea, all cases diagnosed in the current outbreak were asymptomatic [6,13]. However, the predominantly high infection rate in men aged 50 years or older in the present outbreak was in line with previous studies [2,6,14]. This epidemiological investigation showed that all 12 cases of acute hepatitis E from the factory were asymptomatic, but did show HEV IgM-positive results. Therefore, the causative pathogen was presumed to be HEV. Since the virus detected in the human specimens was not detected in the environmental specimens, it could not be determined that the source of infection was through common consumption inside the factory. Furthermore, the epidemiological investigation did not reveal common sources of exposure outside the workplace, such as the use of a common restaurant or other common activities. Acute hepatitis E occurred in 12 of 80 production workers in the factory, accounting for an attack rate of 15.0%. Considering an incubation period of 40 days (range, 15–64 days) from February 2022 when the cases were detected, the infections inside the factory could have occurred between December 2021 and February 2022. Although all cases reported being asymptomatic during the investigation, the DUR of the Health Insurance Review & Assessment Service revealed that 1 case (no. 8) had symptoms of gastroenteritis and colitis and a history of hepatitis E in the past, so the possibility of an index case could not be ruled out. Despite the possibility of co-exposure among all cases, and insufficient evidence for an external environmental route of infection, it was difficult to determine the source of infection.

To prevent the spread of HEV, we monitored for additional cases and anyone presenting with symptoms for the maximum incubation period of 64 days. In addition, follow-ups were conducted with the production workers 2 to 3 months after the outbreak (April 2022). The local public health center collected blood samples from the production workers between April 18 and 19, 2022, and the Department of Virus Analysis at the KDCA analyzed the specimens. In vitro diagnostic agents approved by the Ministry of Food and Drug Safety were used for antibody testing, and the HEV IgM-positive specimens were subjected to additional viral gene detection tests. Three HEV IgM-positive cases (all

c) Raw beef.
previously HEV IgM-positive) and 6 HEV IgG-positive cases (2 previously HEV IgM-positive and 4 previously negative) were found. Among them, 1 case was both HEV IgM- and IgG-positive, and no viral genes were detected in the HEV IgM-positive specimens. The 3 HEV IgM-positive cases had previously tested positive for HEV IgM on February 16, 2022. No new positive cases were detected among the previously HEV IgM-negative workers in the follow-up testing. Although HEV can be detected in blood for 3 to 6 weeks after infection, its detection has also been reported after several months. As all cases showed normal liver function and no symptoms, no further interventions were performed, and the monitoring of the hepatitis E outbreak in the factory ended on April 25, 2022 (Figure S1).

This outbreak investigation had a few limitations. First, because 19 days passed between the time that a diagnosis of hepatitis E was made and the beginning of the on-site epidemiological investigation and collection of specimens, the timeliness of the investigation, the design, and the selection of subjects were not sufficient. Considering the long incubation time of hepatitis E (15–64 days) and the time when the outbreak was first recognized, the on-site epidemiological investigation was conducted at least 1 month after the onset of infections. Therefore, there were no preserved foods on-site that had been consumed by the HEV IgM-positive cases. It was also difficult to obtain cooperation for the investigation from the factory staff. For this reason, we were only able to investigate HEV IgM-positive production workers and not all employees. Thus, the risk of infection from food consumption could not be determined in this case series study. Although the factory cafeteria was used by all employees, the investigation was only conducted among production workers who were subject to routine health examinations, limiting our assessment of the route and location of the infection in this outbreak. In the event of a future hepatitis E outbreak, an appropriate investigation design and selection of subjects is necessary to identify the source and route of infection and to take effective control measures.

Second, the factory had failed to take appropriate measures in the past when cases of hepatitis E were found during annual health examinations of the production workers because the cases had no specific symptoms, and the factory was not aware that hepatitis E was a notifiable infectious disease. According to previous studies [15–17], hepatitis E reinfections can occur despite immunization. HEV IgM-positive individuals convert to negative within 6 months on average, but HEV IgM positivity can last for 2 to 3 years. In this case, it was determined that 3 workers had been HEV IgM-positive in the past due to previous exposure to the virus, with antibodies remaining from the previous infection. In the event of an outbreak of hepatitis E, appropriate case management

F/U, follow-up; IgM, immunoglobulin M; PCR, polymerase chain reaction; IgG, immunoglobulin G; HEV, hepatitis E virus.
measures require timely notification of the disease.

Third, the HEV genotype that caused this outbreak could not be determined because qRT-PCR results from the 12 HEV IgM-positive cases did not show viral genes. In a previous study [18], only 1 of 6 cases with HEV IgM-positive results showed positive qRT-PCR results, indicating that HEV viremia had decreased significantly in the serum of cases with acute symptomatic hepatitis E and, therefore, could not be detected. Further efforts are needed to isolate HEV genes from cases.

Fourth, there is no internationally standardized diagnosis method for hepatitis E, and the possibility of false positives due to the low sensitivity of domestically approved hepatitis E antibody tests cannot be ruled out. According to the results of a previous study in Korea [19], the seroprevalence of HEV IgG in 147 study subjects was 23.1% when tested by Wantai kits (Wantai Biological Pharmacy Enterprise), while the GeneLab (GeneLabs Diagnostics) test for the same group showed 14.3%, indicating a high degree of reproducibility. Therefore, further research is needed on diagnostic methods, including a comparison of the sensitivity and specificity of various hepatitis E antibody test kits.

Despite these limitations in our investigation, this was the first epidemiological investigation and response to a domestic hepatitis E outbreak in Korea. The results of this study suggest the following strategies for domestic hepatitis E control:

First, we should raise awareness regarding hepatitis E and provide information and guidance to healthcare workers to enable an early diagnosis when symptoms manifest. Hepatitis E was designated a class 2 notifiable infectious disease in July 2020. However, because its incidence is low in Korea, and most cases are reportedly asymptomatic, awareness is low among healthcare workers. This leads to frequent omissions or delayed reporting, likely resulting from a low rate of diagnosis even when the infection presents with symptoms. To avoid delays in the reporting of hepatitis E, awareness must be raised.

Second, it is necessary to identify which groups are at risk of infection in Korea to establish effective HEV control strategies. The current outbreak was detected through routine health examinations of production workers required by other countries before exporting the products of the factory. Since hepatitis E is mostly asymptomatic or mildly symptomatic, it is possible to miss hepatitis E even when there is an outbreak. Therefore, it would be helpful to identify domestic risk groups by conducting seroprevalence surveys at the national or regional levels, targeting specific groups with known risk factors.

Third, since HEV can be transmitted zoonotically, hepatitis E needs to be monitored, prevented, and managed using a One Health approach to prevent the spread of HEV from animal hosts to humans [20]. According to recent studies from Europe, Japan, and Australia, HEV genotypes 3 and 4 can lead to zoonotic waterborne or foodborne infections in humans and animals, mainly pigs, boars, and deer [4,6]. It is necessary to establish a system of communication and collaboration among multiple authorities to prepare an integrated governmental response system for infectious diseases, with a focus on the risk factors among people, animals, food, and the environment.

Conclusion

This was the first domestic outbreak of HEV infection to occur in a food manufacturing factory in Korea. Our results may provide useful information for effective outbreak control and the preparation of preventive measures against future domestic outbreaks of HEV infection. Currently, no commercial vaccine has been developed for hepatitis E in Korea. Therefore, to reduce the prevalence of hepatitis E infection and prevent outbreaks, the importance of consuming foods prepared in sanitary settings and fully cooked at the appropriate temperature should be publicly promoted. Raising public awareness of hepatitis E and establishing supportive systems is vital.

ABSTRACT

Objectives: Several previous studies have stated that consuming certain foods and beverages might increase the risk of chronic kidney disease (CKD). This study aimed to examine the relationships of food and beverage consumption with other risk factors for CKD.

Methods: Data sources included the 2018 Basic Health Research (Riskesdas) and the National Socio-Economic Survey (Susenas), which were analyzed using a cross-sectional design. The study samples were households from 34 provinces in Indonesia, and the analysis was performed with provincial aggregates. Data were analyzed using risk factor analysis followed by linear regression to identify relationships with CKD.

Results: The prevalence of CKD in Indonesia was 0.38%. The province with the highest prevalence was North Kalimantan (0.64%), while the lowest was found in West Sulawesi (0.18%). Five major groups were formed from 15 identified risk factors using factor analysis. A linear regression model presented 1 significant selected factor (p = 0.006, R² = 31%). The final model of risk factors included water quality, consumption of fatty foods, and a history of diabetes.

Conclusion: Drinking water quality, fatty food consumption, and diabetes are associated with CKD. There is a need to monitor drinking water, as well as to promote health education and provide comprehensive services for people with diabetes, to prevent CKD.

Keywords: Chronic kidney diseases; Diabetes mellitus; Drinking water; Fatty food

Introduction

Chronic kidney disease (CKD) significantly contributes to the morbidity and mortality caused by non-communicable diseases. Its prevalence has steadily increased worldwide. Although hemodialysis and kidney transplantation are essential modalities that can save the lives of patients with CKD, they are often very expensive. The number of patients who will undergo kidney transplantation is expected to reach 5.4 million by 2030. This condition is increasing most rapidly in low- and middle-income countries. Globally, there are also significant
inequalities in access to high-quality kidney disease treatment, and several low- and middle-income countries cannot meet the increasing need for dialysis [1].

According to the 2017 Global Burden of Disease study, CKD is the 12th leading cause of death. It directly causes about 1.23 million deaths, and 1.36 million additional deaths are associated with cardiovascular disease due to impaired kidney function [2].

During the coronavirus disease 2019 (COVID-19) pandemic, people with CKD were found to develop more severe symptoms of COVID-19 than patients without CKD [3]. Individuals with CKD also have a higher prevalence of hypertension and diabetes, which are associated with higher mortality due to COVID-19 [4,5].

When kidney activity has declined to the point that the kidneys no longer function, then a patient is considered to be in the chronic renal failure phase, which is the final and most severe stage of kidney disease. Medically, CKD is defined as a decrease in the renal filtration rate or the estimated glomerular filtration rate of less than 60 mL/min/1.73 m² for 3 months or more. Patients are deemed to have chronic renal failure when their kidney function decreases to 85% or lower of baseline [6,7].

According to a study conducted in Africa, several factors influence CKD, including a history of hypertension, anemia, a family history of kidney disease, and consumption of coconut oil [8]. Several studies have also reported that diet is related to the incidence of CKD [9–11]. This is reinforced by several other investigations examining the relationship between CKD and the consumption of food and beverages, including foods high in fat and sugar [12], acidic foods [13], cholesterol [14], and drinking water [15,16]. A study conducted in Sri Lanka stated that drinking water with concentrations of cadmium, lead, and fluoride exceeding the maximum limit was associated with chronic kidney damage [17]. Other studies also suggested that high water intake might be associated with slower CKD development [18,19].

Kidney disease has long been a public health problem in Indonesia, and in 2007, it was one of the top 10 causes of death in rural areas in the 5- to 14-year age group [20]. The prevalence of doctor-diagnosed CKD in 2013 was 0.2%, while that of kidney stones was 0.6% [21]. It is estimated that these numbers will continue to increase in the future. In addition, previous studies stated that age, economic status, history of hypertension, sex, history of diabetes mellitus, and obesity [22], consuming energy drinks along with soft drinks [6], and the presence of coronary heart disease, stroke, and comorbidities [23] have a relationship with the occurrence of CKD. However, it is important to note that those previous studies highlighted overall impairments in kidney function, were mostly health facility-based, and were primarily conducted in single sub-districts. Therefore, this study analyzed data from national community-based surveys, focusing on long-standing cases of CKD (i.e., for at least 3 consecutive months), and analyzing the relationships of CKD with dietary patterns, beverage consumption, and a history of comorbidities.

Materials and Methods

Study Design and Sample
This study used a cross-sectional design and secondary data from the 2018 Basic Health Research (Riskesdas) and the National Socio-Economic Survey (Susenas). Riskesdas is a national health survey conducted by the National Institute of Health Research and Development–Ministry of Health in 34 provinces in Indonesia. The target samples included 300,000 households from 30,000 census blocks. Susenas is conducted by the Central Statistics Agency with probability proportional to size sampling derived using a linear systematic sampling method [24].

Dependent Variable
The dependent variable in this study was the prevalence of CKD, measured as a numeric outcome. The related survey question was “Has [NAME] ever been diagnosed by a doctor as suffering from chronic kidney failure? or at kidney disease for least 3 months consistently?” According to the Riskesdas questionnaire interview guideline, CKD is defined according to the Indonesian Nephrology Association as kidney damage both in structure and/or function that lasts for 3 months or more [25].

Independent Variables
This study focused on food intake, beverage consumption, and comorbid conditions that are related to CKD. The independent variables were defined as the percentage of respondents who reported consuming the listed food at least twice per day in the last month. The food consumption habits comprised salty, flavored, fatty, and grilled food, as well as foods with preservatives, instant food, sugary beverages, soft and energy drinks, alcohol, and plain drinking water. Smoking behavior and hygienic behavior (handwashing) were also investigated. In addition, participants’ history of comorbid diseases (e.g., hypertension or diabetes mellitus) was also included as an independent variable.

The drinking water quality variable was defined referring to the guidelines from the Joint Monitoring Program (World Health Organization [WHO]/United Nations International
Study Tools
The 2018 Riskesdas and Susenas reports were used as a tool in this study. From these 2 reports, the independent and dependent variables were obtained and recorded in Excel (Microsoft Corp.) as a new subset of data for further analysis.

Instrument reliability and validity
Cronbach's alpha is a measure of internal consistency, and its values range from 0 to 1. A value greater than 0.60 is considered to indicate that an instrument is reliable and acceptable. A high Cronbach's alpha shows that the items in an instrument are highly correlated [30].

Statistical Analysis
Since this study aimed to identify foods and beverages associated with the prevalence of CKD, it started by identifying several types of foods and beverages that were frequently consumed by survey participants, as well as their history of comorbid conditions. Fifteen variables were analyzed: salty, flavored, fatty, and grilled food; foods with preservatives; instant foods; sugary, soft, and energy drinks; alcohol; and plain drinking water. In addition, smoking behavior, personal hygiene, and comorbidities such as diabetes mellitus and hypertension were analyzed to determine their relationship with CKD.

First, a descriptive analysis was performed. The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy, which has values ranging from 0 to 1, was used to test the feasibility of factor analysis. A KMO value > 0.5 indicates that factor analysis is feasible [31]. Bartlett test of sphericity is a statistical test to test whether variables are correlated. A significant value (< 0.05) indicates that there is a relationship among the variables [31].

Next, factor analysis was performed to reduce the number of the original variables by examining the covariance before conducting linear regression. The basic purpose of factor analysis is to identify relationships between variables by conducting a correlation test. It is useful to apply factor analysis to focus on only a few manageable factors rather than a large number of variables [31]. Meanwhile, linear regression was carried out to determine the relationship between CKD and the factors that were formed. All statistical analyses were performed with IBM SPSS ver. 21.0 (IBM Corp.).

Ethics Approval
Ethical approval and permission for conducting this study followed the Ethical Approval for RISIKESDAS 2018 from Komisi Etik Penelitian Kesehatan, Badan Penelitian dan Pengembangan Kesehatan (Ethical Committee of Health Research, National Institute of Health Research and Development–Ministry of Health, Republic of Indonesia) No. LB.02.01/2/KE.267/2017.

Results
Overview of CKD Prevalence and Risk Factors
Data on CKD collected from 34 provinces in Indonesia in 2018 were analyzed. The average prevalence was 0.38%, meaning that 4 out of 1,000 people were diagnosed with CKD. The highest prevalence was found in North Kalimantan Province, while the lowest was in West Sulawesi, as shown in Figure 1.

Figure 2 shows several bars and points representing the conditions of each province. The blue bars represent the percentage of respondents with good water quality, while the percentages of food/beverage consumption, comorbidities, and handwashing behavior are represented by dots. A greater number of dots displayed at the top of the bar indicates a higher risk of CKD in the province. In general, the quality of drinking water in all provinces was moderate, with the highest percentage of good water quality occurring in Capital Region (Daerah Khusus Ibukota) Jakarta Province. Furthermore, the percentage of flavored food consumption was very high in almost all provinces.

The highest percentage of fatty food consumption was found in Central Java Province, while the highest percentage of alcohol consumption was in North Sulawesi. Salty foods were most frequently consumed by residents in West Java Province, while sweet beverages were most frequently consumed in Yogyakarta Province, as shown in Figure 2.
Figure 1. Prevalence of chronic kidney disease by province in Indonesia, 2018.

Figure 2. Candidate factors associated with chronic kidney disease by province in Indonesia, 2018.
Descriptive Statistics and Factor Analysis
This study used factor analysis to extract a smaller set of variables from the large number of original variables to make linear regression more manageable. Fifteen independent variables were assumed to have a relationship with CKD. To analyze the associations of variables, the KMO method was used to measure the suitability of data for factor analysis. As shown in Table 1, the KMO statistic was 0.559. This value was > 0.5, which indicates that sampling was adequate. The Bartlett test of sphericity value was 292.42, with a significance of < 0.001, which met the requirements because the significance was below 0.05 (5%).

Table 1 shows the eigenvalues and total variance obtained from principal component analysis. Before extraction, 15 linear components were identified within the data set. After extraction and rotation, there were 5 distinct linear components within the data set with eigenvalues > 1. These 5 factors accounted for a combined 78.3% of the total variance. This is supported by the KMO value of 0.559, which can be considered adequate and also indicates that factor analysis was useful for the variables.

Extraction method: principal component analysis. Initial eigenvalues < 1, then factor of extraction sum of squared loading cannot be formed.

Reliability and Validity
Validity tests were carried out to determine the precision of the variables used, while reliability tests were performed to analyze the internal consistency through Cronbach’s alpha. A validity value ≥ 0.5 is considered satisfactory, while the adequate threshold value for Cronbach’s alpha is ≥ 0.6 [30]. In this analysis, the validity value was 91.9%, while Cronbach’s alpha of the 15 variables was 0.622; thus, both thresholds were exceeded. This shows that the variables exhibited correlations with their component grouping, meaning that they were internally consistent.

Multivariable Linear Regression
To identify risk factors associated with CKD, multivariable analysis was performed on the 5 factors. Table 3 shows the multivariate model of linear regression analysis of the 5 factors in relation to CKD. The model showed an $R^2$ of 31% and a significant p-value, as demonstrated in Table 3. Factor 3, which comprised the quality of drinking water, fatty foods, and diabetes, showed a significant relationship with CKD. The final model, which contained water quality, fatty food, and diabetes, had a significant association with CKD.

The 5 factors formed were as follows. Factor 1 consisted of grilled food, food containing preservatives, instant food, soft drinks, and energy drinks. Factor 2 comprised sweet and salty foods, alcoholic beverages, and hypertension. Meanwhile, factor 3 consisted of the quality of drinking water, fatty foods, and diabetes, while the components in factor 4 included hygienic behavior and food flavorings, and factor 5 consisted of smoking behavior.

Discussion

Main Findings
The results showed that the risk of CKD was relatively high in people who often consumed fatty foods, drank unhealthy water, and had diabetes mellitus. The highest prevalence was found in North Kalimantan Province.

Factors Associated with CKD
Based on the results, people who drink unhealthy water are more likely to develop CKD than those who consume quality water. This is most likely due to the presence of chemical substances and minerals associated with impaired kidney function in poor-quality water. Arsenic exposure is associated with the risk of end-stage renal disease, and this effect is modified by comorbidities, which should be treated in the early stages [32]. Water from wells with higher levels of total dissolved solids and arsenic had a positive correlation with the occurrence of CKD [16]. Furthermore, consuming drinking water from dug wells contaminated with cadmium, lead, and fluoride can increase the prevalence of CKD [33,34]. Soil contamination with toxic metals and fluoride presumably comes from agricultural fertilizers in the long term, which continuously causes groundwater contamination [17]. Balanced levels of minerals in drinking water have a beneficial effect on kidney health [35]. There is also a need to strengthen the water quality surveillance system to reduce the risk of disease. This is important for achieving the Sustainable Development Goal targets for improving water quality and identifying populations at risk [36].

The results also showed that people who consumed more fatty foods were more likely to have CKD. This is consistent with a previous study that stated that consuming a high-fat diet was associated with a significant increase in the likelihood of developing CKD [12]. In contrast, the consumption of fruits and vegetables, along with a lower intake of red and processed meat, is associated with a reduced incidence of CKD [10]. Another study suggested that a low-acid diet slows the development of CKD [13].

The analysis also showed that comorbid diabetes mellitus might increase the occurrence of CKD. Subjects with diabetes mellitus are more likely to develop CKD than normal individuals. However, diabetes care has been found to be associated with a decreased risk of developing kidney disease [37]. Moreover, comprehensive care is recommended for the management of patients with diabetes and kidney disease to prevent cardiovascular disease. For example, moderate physical activity of at least 150 minutes per week is recommended, along with smoking cessation, reducing obesity, salt restriction, and a low-protein diet [38].

Based on the results, there is a need to increase the monitoring of drinking water for public consumption. In addition, it is important to increase public knowledge about the risks associated with excessive consumption of fatty foods, as well as comprehensive care for patients with

CI, confidence interval.
diabetes, including a healthy lifestyle to prevent severe disease. It is assumed that the relationships of CKD with the quality of drinking water and fatty foods have great potential for further investigations using other methods and designs, such as cohort studies supported by comprehensive laboratory examinations.

**Strengths and Limitations**
The major strength of this analysis is that it used data from the results of a national public health survey. This implies that it can describe the prevalence of the disease nationally with a large sample, but there were also limitations. As a national health survey with a cross-sectional method, water quality and disease were evaluated based on interviewees’ statements using a structured questionnaire, not based on the results of laboratory measurements.

**Conclusion**
This study found a relationship between CKD and unhealthy drinking water, excessive fatty food consumption, and a history of diabetes mellitus. Based on these results, there is a need to safely manage drinking water and increase public knowledge about the risks of consuming fatty foods to reduce the risk of CKD. Comprehensive care for patients with diabetes and a healthy lifestyle are also important to prevent disease progression.

ABSTRACT

Objectives: This study was conducted to determine the impact of the strengthening or relaxation of face covering mandates on the subsequent national case incidence of coronavirus disease 2019 (COVID-19) in Europe as the full vaccination rate was increasing.

Methods: European countries in which case incidence increased for 3 consecutive weeks were monitored and analyzed using COVID-19 incidence data shared by the World Health Organization (WHO). The epidemic trend of COVID-19 in Europe was compared with that of countries elsewhere in the world based on WHO weekly epidemiological reports from June 20 to October 30, 2021. In addition, this study provided insight into the impact of government mask mandates on COVID-19 incidence in Europe by measuring the index scores of those facial covering policies before and after mandate relaxation or strengthening. The effects of the vaccination rate and the speed of vaccination on COVID-19 incidence were also analyzed.

Results: The incidence of COVID-19 after the relaxation of face covering mandates was significantly higher than before relaxation. However, no significant difference was observed in vaccination rate between countries with increased and decreased incidence. Instead, rapid vaccination delayed the resurgence in incidence.

Conclusion: The findings suggest that face covering policies in conjunction with rapid vaccination efforts are essential to help mitigate the spread of COVID-19.

Introduction

The outbreak of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), the virus responsible for coronavirus disease 2019 (COVID-19) first identified in Wuhan, China in December 2019, led to a global pandemic [1]. By October 2021, the COVID-19 pandemic was
in its second year in Europe, which had again become the center of the global epidemic. Although over 2.8 million COVID-19 cases were reported in the week of October 4–10, 2021, the weekly number of new cases reported globally had continued to decline since late August 2021 after increasing for nearly 2 months since mid-June 2021 [2]. While the incidence of COVID-19 cases was decreasing globally, Europe had experienced a plateau in incidence starting at the end of July 2021; then, in the third week of September, the number of new cases began to increase, with European countries accounting for most of those with increased incidence for the third consecutive week [2,3]. Over half of the European countries (42 of 61, 68.9%) exhibited an increase in the number of new cases during the week of October 18–24, accounting for more than half (57%) of the weekly new cases worldwide and making Europe the only world region reporting an increase in cases [4]. According to some studies, the spread of COVID-19 increased not only in Russia and eastern Europe, where vaccine coverage is significantly lower than elsewhere, but also in European countries with high vaccination rates that implemented “living with COVID-19” strategies (most notably, removing some requirements for facial coverings) [5,6].

Although vaccinated individuals appear to be well protected against serious symptoms [7], vaccination has little effect on the disruption of the infection chain necessary to restrain the epidemic [8]. Moreover, achieving high coverage is difficult given the complexity of large-scale vaccine production, distribution, and uptake [7]. This indicates a need to continue with non-pharmacological interventions (NPIs), such as physical distancing and wearing face coverings, as long as a substantial proportion of individuals remain unvaccinated [9,10]. As the emergence of variants and the weakening of immunity can also reduce vaccine effectiveness [7,8], the prevention of new infections is limited even in countries with high vaccination rates. One study on the resurgence of COVID-19 in a highly vaccinated healthcare workforce emphasized that the rapid reintroduction of NPIs, including the wearing of face coverings indoors, can counter the rapid spread of a new viral variant [11]. Moreover, many children have not yet been vaccinated, and young children are not required to wear face coverings in numerous countries [12]. This suggests that government countermeasures, such as the compulsory wearing of face coverings even for vaccinated adults, are required. Many countries have increased compliance with mask-wearing by strengthening mandates in various settings [13]. An analysis showed that these laws and regulations were effective in raising compliance with mask-wearing and delaying the spread of COVID-19 [14,15]. In many studies on the impact of face coverings on virus transmission, the period of mandatory masking has been used for analysis [16]. At the start of the 2021–2022 school year, in the 2 largest counties of the United States (US) state of Arizona, schools with a face covering mandate were 3.5 times less likely to experience a school-related COVID-19 outbreak than schools without one [17].

As vaccination rates improve, demand is increasing to relax COVID-19 guidelines, despite most of the populations in question remaining remaining susceptible [18]. In 2021, the rate of mask-wearing declined significantly worldwide, including in countries with low vaccination rates [16]. However, due to the risk of another wave of infections, the appropriate time to lift quarantine restrictions remains uncertain [18]. Recent mathematical modeling indicates that if NPIs are relaxed too early—before immunity has been fully established—a large outbreak may occur, resulting in hospitalization and death [1]. Although an abrupt weakening of NPIs may result in a similar number of deaths as a prolonged infection wave under a gradual relaxation of NPIs, a more extended infection period with a smaller outbreak provides a much greater chance for future interventions to be effective and reduces stress on the health care system [1].

Given the ongoing epidemic, we must evaluate the effectiveness of mask-wearing after some immunization progress has been achieved [19]. Although evidence for the effective impact of face coverings on COVID-19 transmission has accumulated at the individual level, the additional benefit of national mandates is less certain. We focused on the impact of the legal requirement to wear a face covering on the national weekly case incidence of the disease by analyzing the strength of government masking policies in European countries. In this study, we aimed to analyze the association between the strength of face covering mandates and national COVID-19 case incidence by quantifying the government policy indicators of such mandates and the trend of vaccination rates in European countries. In addition, we attempted to assess whether the protective effect of vaccination and masking mandates could reduce COVID-19 case incidence at the national level.

**Materials and Methods**

The study targeted 25 European countries with an increase in COVID-19 cases for 3 consecutive weeks between September 19 and October 30, 2021 (Russia, Ukraine, Romania, Bulgaria, Republic of Moldova, Georgia, Belarus, Poland, Czech Republic, Austria, Denmark, Lithuania, Estonia, Latvia, the Netherlands, Belgium, Greece, France, Germany, Portugal, Azerbaijan, Norway, Turkey, Hungary, and Ireland) and
10 countries with a decrease or no increase in cases for 3 consecutive weeks (Italy, Spain, Sweden, Switzerland, Slovenia, Albania, Serbia, Bosnia and Herzegovina, Croatia, and Cyprus). The number of weekly confirmed cases by country was calculated based on the new daily COVID-19 incidence data shared by the WHO, and countries in which the number of cases increased for 3 consecutive weeks were monitored. In addition, WHO weekly epidemiological reporting was used to compare the trend of the COVID-19 outbreak between Europe and other world regions. The data collection period was from June 20, 2021 (when the number of new cases and countries with increasing COVID-19 cases for 3 consecutive weeks began to increase simultaneously) to October 30, 2021, before the first case of the Omicron variant was reported in Europe.

The government response regarding mandatory masking was quantified using the facial coverings section corresponding to the health system among the 23 policy indicators of governmental COVID-19 response. These indicators were presented by the Oxford COVID-19 Government Response Tracker of the Blavatnik School of Government at Oxford University in the United Kingdom. Based on rules regarding the use of facial coverings outside the home, government policies were scored as 0 (no policy), 1 (recommended), 2 (required in some specified shared/public spaces outside the home with other people present or some situations in which social distancing was not possible), 3 (required in all shared/public spaces outside the home with other people present or all situations in which social distancing was not possible), or 4 (required outside the home at all times regardless of location or presence of other people). We calculated the average vaccination rate over 2 weeks to investigate any difference in incidence or case growth rate based on the rate of fully vaccinated people by country. A US Centers for Disease Control and Prevention (CDC) study indicated that about 2 weeks are required after vaccination for the body to produce antibodies that protect against infection. That study also showed that the risk of infection is reduced by 90% following the second dose of vaccine [20]. In the present study, national vaccination rates were classified as 0 (<40%), 1 (40% and <60%), or 2 (≥60%) based on the number of fully vaccinated people provided by Our World in Data. Incidence refers to the number of weekly new COVID-19 cases per 100,000 people in each country.

We analyzed the correlations among the incidence or growth rate in COVID-19 cases, the strengthening or relaxation of face covering policies, and the vaccination rate. Regarding face coverings, we investigated whether the mandates were relaxed at least once along with the index scores of those facial covering policies during the 7 weeks immediately prior to the start of the increase in cases. One study showed that new COVID-19 cases peaked 45 days after the lifting of masking mandates [21]. Thus, changes in face covering policies and the associated index scores were observed for 7 weeks. In addition, the t-test was conducted for the incidence and the case growth rate before and after the mandatory wearing of face coverings was eased or strengthened. The index scores of the facial covering policies and vaccination rates were also analyzed using t-testing for the 25 countries in which the incidence increased for 3 consecutive weeks and the 10 countries in which incidence decreased or did not increase during that period. In a further analysis, we examined the time for 26 countries to reach 40% fully vaccinated by October 30, 2021, along with the amount of time taken for the re-increase in COVID-19 incidence after the 40% vaccination threshold. The basis for the vaccination threshold of 40% was the global COVID-19 vaccination strategy and time-bound coverage target announced by the WHO [22]. The WHO warned that the risk of emergent vaccine-resistant variants may continue if the 40% vaccination target cannot be reached [23]. The International Monetary Fund staff also proposed that at least 40% of the population in all countries should be vaccinated by the end of 2021 to bring the pandemic under control [24]. Thirteen countries (Latvia, France, Portugal, Azerbaijan, Norway, Turkey, Italy, Spain, Sweden, Switzerland, Serbia, Croatia, and Cyprus) began to see a resurgence in incidence within 3 months of achieving 40% vaccination coverage. The other 13 countries, which displayed no increase in disease incidence within 3 months of achieving 40% vaccination coverage, were Poland, Czech Republic, Austria, Denmark, Lithuania, Estonia, Netherlands, Belgium, Greece, Germany, Hungary, Ireland, and Slovenia. Of the 13 countries in which 13 weeks or more elapsed before a re-increase in incidence after a vaccination rate of 40% was achieved, 11 countries (accounting for approximately 42% of the total countries) took 13 weeks, while the rest of the 13 countries took more than 13 weeks. Accordingly, the speed of vaccination was compared between countries reaching 40% before and after 3 months. For countries with 2 or more re-increase periods after achieving 40% vaccination coverage, the re-increase period was defined from the week of the interval including the week with the highest incidence. Analysis of variance was used to evaluate the significance of differences in the average incidence or the case growth rate in the 25 countries according to the average vaccination rate for 2 weeks immediately before the increase in cases for 3 consecutive weeks.

**Statistical Analysis**
All statistical analyses were conducted using Rex ver. 3.6.3 excel-based software (Rexsoft Co.; http://rexsoft.org).

**Results**
To identify trends in COVID-19 cases, we followed the CDC criteria to monitor weekly changes in the number of cases over a 4-week period by country. The CDC has provided a line graph on a monthly basis to visualize trends in the number of US COVID-19 cases. The correlation between the average incidence or weekly case growth rate per 100,000 population over 4 weeks for countries in which the incidence increased for 3 consecutive weeks and countries that relaxed the mandatory mask-wearing criteria at least once in the 7 weeks immediately before the increase was positive ($r = 0.339, 0.388$) (Tables 2, 3). However, negative correlations ($r = -0.204, -0.260$) were found between the average incidence during the 4 weeks of increase and the average vaccination rate for the 2 weeks immediately before the increase and during the 4 weeks of increase, respectively (Table 4). This finding showed that the implementation of face covering mandates was necessary to prevent the spread of COVID-19 at the national level. The incidence rate in the 2 weeks after reinforcement

of mandatory masking policies was higher than in the 2 weeks before reinforcement, while the case growth rate was lower in the 2 weeks after strengthening of masking policies; however, neither change was statistically significant (Table 5).

In contrast, no significant difference in average vaccination rate was observed in the 2 weeks immediately before the increase or decrease in incidence between countries with increasing and decreasing incidence (Table 6).

In addition, countries with an average vaccination rate of 60% or higher for the 2 weeks immediately prior to the 4-week increase showed decreases in the average incidence and case growth rate during the increase compared to countries with vaccination rates at or above 40% and less than 60%, but this was not statistically significant (Figures 1, 2). Furthermore, by analyzing the time taken for the re-increase in incidence after reaching the 40% vaccination threshold and the time to reach a fully vaccinated rate of 40%, we concluded that countries in which the incidence began to increase again after 3 months took significantly less time to reach 40% vaccination than countries where the incidence began to re-increase within 3 months (Table 7).

### Discussion

This study showed the impact of face covering mandates and vaccination coverage on the incidence of COVID-19 in 35 European countries from June 20 to October 30, 2021. The average COVID-19 case incidence in countries where incidence increased for 3 consecutive weeks was significantly higher than in countries where cases decreased or did not increase during that period (Table 1). Furthermore, relaxation of face covering mandates was associated with an increase in the incidence of COVID-19 (Tables 2–4). Six US states (North Dakota, Iowa, Montana, Texas, Wyoming, and Arkansas) lifted face covering mandates between January and March 2021. As indicated by an event study analysis, daily new cases began to increase within 9 to 15 days after the mandates were lifted, followed by the highest increase (12 cases per 100,000 people).

*Three consecutive weeks of increasing incidence (between September 19 and October 30, 2021). *Three consecutive weeks of decreasing or no increase in incidence (between September 19 and October 30, 2021). *Three consecutive weeks of increasing or decreasing incidence.
on day 45 [20]. This result implies that policies mandating mask-wearing in public needed to be strengthened, given that some states demanded or initiated the lifting of face covering obligations around that time [21]. We also found an increase in incidence and a decrease in the case growth rate after 2 weeks of reinforcement of face covering mandates, but neither finding was statistically significant (Table 5). The enforcement of mask-wearing may take longer than desired because behavior change reinforcement must disrupt current habits and simultaneously encourage a new and unfamiliar set of behaviors [26]. According to Layyy et al. [27], it takes 18 to 254 days for a person to form a new habit and an average of 66 days for a new behavior to become automatic. COVID-19 incidence may continue to increase in the early stages of strengthening of face covering mandates. Given the decrease in the case growth rate, however, the incidence could also decline over time. One study [28] showed that strengthening of face covering mandates in most or all shared or public places between August 2020 and January 2021 in 114 regions of 8 European countries reduced the reproduction number by 12% (95% confidence interval [CI], 7%–17%). Before the onset of the second wave of infection, these countries had implemented policies that mandated face coverings in only some public places. Thus, the advantage of wearing a face covering is expected to be realized when strengthened masking mandates are implemented [28]. Similarly, a 2% decrease in the growth rate of daily cases, constituting a significant difference, was observed at ≥21 days after masking became compulsory in a natural experiment including 15 US states [14]. In another study, the effectiveness of wearing a face covering was tested using mathematical modeling tools, with the results showing that public masking could considerably slow the spread of COVID-19 and prevent further outbreaks of the disease [29]. These findings demonstrate that face coverings are effective in protecting non-infected face-covering wearers from acquiring the disease and preventing infected wearers from transmitting the disease to others [13,16,30–32]. Therefore, governments must strongly encourage the use of face coverings in various public places using regulations [13].

In contrast, as seen in Table 6, no significant difference was present in vaccination rates between countries with increasing and decreasing incidence, which indicates that the increase or decrease in COVID-19 incidence may have little correlation with the level of vaccination. In fact, a national-level study revealed no perceptible relationship...
between the fully vaccinated percentage of the population and new COVID-19 cases across 68 countries [33]. Iceland and Portugal, where more than 75% of the population had been fully vaccinated, had more COVID-19 cases per 1 million people than countries such as Vietnam and South Africa, where about 10% of the population had been fully vaccinated. In the US, 2947 counties also showed no significant decline in COVID-19 cases as the percentage of fully vaccinated population increased [33]. The US CDC identified 4 of the 5 counties with the highest percentage of fully vaccinated population (84.3%–99.9%) as high-transmission counties [33]. Conversely, counties with less than 20% of the population fully vaccinated accounted for 26.3% of the 57 counties classified by the CDC as low-transmission counties. This suggests that NPIs, such as masking, should be implemented as vaccination rate increases [33]. From the end of June 2021, the number of European countries demanding or implementing the relaxation or lifting of face covering mandates has increased [6]. Perhaps people can wear less face coverings with the relief after COVID-19 vaccination [21]. However, a sizable proportion of Europe was vulnerable to infection in July 2021. At that time, just 35% of adults in the Europe and European Economies Area (including Iceland and Norway) were fully vaccinated, and Russia and other former Soviet Union countries had barely reached a 10% vaccination completion rate [6]. In addition, European civil officials appeared reluctant to adopt a culture of mask-wearing, which in Asian countries after the influenza epidemics of 1918, 1957, and 1968 and the SARS-CoV-1 outbreak in 2002 has been prevalent as an effective measure for epidemic containment [6]. The European Centers for Disease Control and Prevention has issued a risk assessment urging strict adherence to public health measures that have previously worked to control the effects of different variants [34]. The WHO has urged “extreme caution” for countries considering lifting COVID-19 restrictions, warning that high vaccination rates will not prevent the growing transmission of the virus [35]. Furthermore, the virus is still evolving and changing, and it is unclear to what extent vaccination provides protection against becoming infected or spreading the virus to others [35]. A recent study re-emphasized the difficulty of controlling the COVID-19 pandemic with vaccination alone [7]. This study also showed that the incidence of the disease increases again upon the cessation of masking when a certain range of vaccination rate has been achieved [7]. This is because reaching a certain vaccination level does not immediately stop the spread of the virus. Alternatively, wearing a face covering could prevent further COVID-19 cases until transmission finally begins to wane after 2 to 10 weeks [7]. Simulation outcomes of another study also suggested that eliminating NPIs (such as movement restriction and mask-wearing) while COVID-19 vaccines are being delivered may considerably increase infections, hospitalizations, and deaths compared to a situation in which NPIs are maintained [36]. These results emphasized that the 2 strategies of increasing the vaccination rate and adhering to sustainable NPIs (such as masking) should be combined to safely return to pre-COVID-19 pandemic conditions [36]. This combination is potentially synergistic because vaccination protects against the disease while face coverings interfere with virus transmission using a physical barrier to any coronavirus variant [8].

In addition, as shown in Figures 1 and 2, the number of new COVID-19 cases per 100,000 people increased until the countries achieved a vaccination rate of 60% of their total populations, but decreased after reaching 60% vaccination coverage. This result resembles that of a study in which the number of new cases per million people and the reproductive rate of COVID-19 slowly decreased as the vaccination rate increased, with a marked decrease when the vaccination rate exceeded 60% [37]. However, as of August 20, 2021, COVID-19 vaccination rates had not reached 60% on any continent, meaning that the vaccination rates were too low to prevent disease transmission [37]. In addition, this study showed that the faster a certain vaccination level was reached, the longer it took for the incidence to re-increase (Table 7). The results indicate that a rapid rise in the COVID-19 vaccination rate attenuates the intensity of the epidemic, extending the time to prepare for a resurgence. A scenario analysis by Wang et al. [38] in 2022 showed that accelerating the vaccination speed in the early stages of a vaccination campaign can reduce infections and increase vaccine effectiveness. In a scenario involving a doubled speed of vaccination, the vaccine effectiveness increased to 77.5% (95% CI, 29.2%–93.6%), averting an additional 1.71 million cases. By contrast, when the vaccination speed was halved, predicted vaccination effectiveness declined to 43.7% (95% CI, 9.34%–70.2%), with 2.55 million more infections. Therefore, the speed of vaccination from the beginning of the vaccination campaign is crucial, given the spread of new COVID-19 variants and the need for booster shots [38]. The simulation model of another study showed that reaching 80% vaccination while maintaining masking could avoid 7.66 million SARS-CoV-2 cases [7]. However, achieving this range 2 months later could prevent 8.57 million cases. These results emphasize the need for continued adherence to masking in addition to the rapid implementation of vaccination.

This study has several limitations. During the re-spreading
of COVID-19 in Europe, a confirmed European case of the Omicron variant was reported, limiting the extension of the study period. Moreover, it was difficult to measure the independent impact of mandatory masking because European countries implemented multi-layered infection prevention and control measures, and this study examined COVID-19 incidence only at the national level. Lastly, of the 25 European countries selected for the study, Eastern European countries accounted for 44% (11 countries), or nearly half. This is due to limitations on the availability of the index scores of masking policies and vaccination rate. Thus, assessing the effectiveness of face covering mandates in Europe with more data from other European countries may help generalize our findings.

Conclusion

The hasty easing or lifting of face covering mandates along with increasing vaccination rates has resulted in a resurgence of COVID-19 infection in European countries. Not all countries on the same continent can vaccinate with equal speed, and the effects of masking at the national level may depend on government mandates. Hence, we strongly recommend policymakers proceed cautiously regarding the adjustment of face covering mandates to avoid a resurgence of COVID-19 incidence. Further control of the COVID-19 epidemic at the national level should allow for an effective vaccination campaign. It would also be wise to appropriately plan for effective and sustainable face covering mandates until the vaccination rate reaches a certain level.

ABSTRACT

Objectives: We evaluated pain, fatigue, anxiety, depression, and quality of life in patients hospitalized for coronavirus disease 2019 (COVID-19) and observed them over a period of 3 months. We also investigated the relationship of these symptoms to age, sex, disease severity, and levels of anxiety and depression.

Methods: The study included 100 confirmed COVID-19 patients (i.e., positive on a polymerase chain reaction test) between the ages of 18 and 75 years. Pain (visual analog scale [VAS]), fatigue (fatigue severity scale), anxiety, and depression (hospital anxiety and depression scales) were evaluated on the first day of hospitalization and at 1-month and 3-month follow-ups. The short form-12 questionnaire was used to measure quality of life at the 1-month and 3-month follow-ups.

Results: No differences were found in pain, fatigue, anxiety levels, depression levels, and quality of life according to disease severity. High VAS scores at hospital admission were related to continued pain at the 3-month follow-up (odds ratio [OR], 1.067; \( p < 0.001 \)). High VAS (OR, 1.072; \( p = 0.003 \)) and anxiety levels (OR, 1.360; \( p = 0.007 \)) were related to severe fatigue at the 3-month evaluation.

Conclusion: Pain, fatigue, anxiety, and depression appear to be long-term sequelae of COVID-19 and can affect quality of life. High VAS and anxiety levels were found to be associated with long-term fatigue.

Keywords: COVID-19; Fatigue; Pain

Introduction

On February 11, 2020, the World Health Organization (WHO) named a new disease caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), coronavirus disease 2019 (COVID-19), and declared the COVID-19 pandemic on March 11, 2020 [1]. Since then, the virus has spread rapidly around the world. As of June 2022, more than 535 million people had been...
infected with COVID-19, and 6 million had died [2].

COVID-19 can affect all age groups, from infants to the elderly, and manifests as a viral disease with a wide range of clinical symptoms, of which fatigue, fever, and cough are the most common [3]. The most frequent musculoskeletal symptoms are myalgia, arthralgia, back pain, and fatigue, which can be seen from the onset of symptoms through the most severe stages of the disease [4–6]. Symptoms such as fatigue and dyspnea have been shown to persist beyond the acute stage to long after discharge from the hospital, emphasizing the importance of long-term follow-up and the rehabilitation therapy needs of COVID-19 patients [7]. References to long-term COVID or post-COVID syndrome have come to the fore. The National Institute for Health and Care Excellence defines post-COVID syndrome as "signs and symptoms that develop during or after an infection consistent with COVID-19 that last more than 12 weeks and cannot be explained by another diagnosis" [8].

The current literature supports the premise that pain in COVID-19 patients is due, at least in part, to the neurotropism of SARS-CoV-2. Pain can be caused by the interaction of the virus with the angiotensin-converting enzyme isoform 2 receptors in spinal neurons and microglia, by immune system-mediated inflammation, or by viral damage [9].

Pain and fatigue dramatically affect quality of life. In one study, the quality of life was found to be worse in COVID-19 patients with persistent pain [10], but the factors associated with these persistent symptoms were unclear. In this study, we evaluated musculoskeletal symptoms such as pain and fatigue, levels of anxiety and depression, and the quality of life in patients hospitalized for COVID-19 and followed them for 3 months. We also investigated how their symptoms were linked to age, sex, disease severity, and levels of anxiety and depression.

**Materials and Methods**

**Participants**

This was a single-center cohort study that included confirmed COVID-19 (i.e., polymerase chain reaction positive) patients between ages 18 and 75 years who were hospitalized at the Afyonkarahisar Health Sciences University Hospital, Pandemic Service between February 15, 2021 and July 15, 2021 and voluntarily agreed to participate.

We excluded patients who were unwilling, illiterate, or pregnant and patients with a history of chronic pain or fatigue during the past 6 months (before COVID-19). We also excluded critically ill patients with respiratory failure requiring mechanical ventilation, shock, or organ failure requiring admission to the intensive care unit (ICU). Patients who were later taken to the ICU or who could not be reached during the follow-up period were excluded.

A total of 242 patients were hospitalized with a diagnosis of COVID-19 at the Afyonkarahisar Health Sciences University Hospital between February 1, 2021 and July 1, 2021. Forty-two patients were >75 years old, 19 did not want to participate, 26 had chronic fatigue and pain symptoms, 8 were illiterate, and 6 were pregnant. Thus, 141 patients were assessed for eligibility. Of the 141 patients, 21 could not be reached for follow-up by telephone, 5 had communication problems due to language differences, and 15 were transferred to the ICU. Therefore, the remaining 100 patients were contacted and completed the questionnaire (Figure 1).

**Assessments**

**Pain**

For the pain assessment, we used the visual analog scale (VAS), which is easy to understand, apply, and interpret. It provides valid and reliable data in a short time. Using a visual linear scale of 100 mm, the patient was told that point 0 represented no pain and point 100 represented the most severe pain they had ever felt in their life. The patient was asked to put a mark on the point corresponding to his/her pain. Patients who marked a VAS score of more than 4 mm were considered to have pain [11]. In addition, we determined the location of their pain (neck, back, low back, upper extremity, lower extremity).

**Figure 1.** Diagram of patient sample selection and exclusions (boxes on the right). COVID-19, coronavirus disease 2019; ICU, intensive care unit.
Fatigue
Fatigue was evaluated using the Turkish version of the fatigue severity scale (FSS). The FSS consists of 9 items, and each item is scored on a 7-point scale from 1 to 7 (1, strongly disagree; 7, strongly agree). The total score is calculated by deriving the arithmetic mean. In our study, patients were considered to have severe fatigue if the total FSS score was ≥4 [12].

Anxiety and depression
We used the hospital anxiety and depression scale (HADS) to determine the risk of anxiety and depression in patients and to determine its level. The HADS consists of 2 subscales to evaluate anxiety and depression, and the cutoff scores in the Turkish version are 10 for the anxiety subscale and 7 for the depression subscale [13].

Quality of life
The short form-12 (SF-12) was used to evaluate patients’ quality of life. The SF-12, a shortened and simplified version of the SF-36, is an easy-to-administer questionnaire. It assesses the 2 main components of general health, physical and mental health, and consists of 12 questions. High scores indicate good health.

Patients' demographic information was obtained including comorbidities, initial COVID-19 symptoms, vaccination status, and drugs used by the patient. Pain, fatigue, anxiety, and depression were evaluated on the first day of hospitalization (initial) and at the 1-month and 3-month follow-ups. The 1-month and 3-month patient evaluations were conducted over the telephone. In these phone interviews, answers to the SF-12 questionnaire were used to measure the patients’ quality of life, pain, fatigue, anxiety, and depression.

A patient’s COVID-19 illness was classified as mild, moderate, or severe according to the severity of their symptoms. Levels of pain, fatigue, anxiety, depression, and quality of life were compared according to disease severity. The disease severity classification was determined based on the clinical management guidelines for COVID-19 published by the WHO. Patients without evidence of pneumonia or hypoxia were classified as mild cases. Patients with clinical signs and symptoms of pneumonia but no signs of severe pneumonia and no need for oxygen were classified as mild cases. Patients with signs and symptoms of pneumonia, a respiratory rate of more than 30 breaths per minute, severe respiratory distress, or a saturated oxygen level in room air of < 90% were considered severe cases [14].

The correlations between symptoms and quality of life were investigated. In addition, the factors that could predict pain and fatigue at the 3-month follow-up were assessed.

Statistical Analysis
The statistical analysis was performed using IBM SPSS ver. 20.0 (IBM Corp.). The distribution of continuous variables was evaluated using the Shapiro-Wilk test. For descriptive statistics, the number of units, percent, and median (range) values were given. For comparisons of 2 independent groups using nonparametric data, the Mann-Whitney U-test was applied. A Spearman correlation analysis was used to evaluate the associations between quantitative variables. Prior to logistic regression analysis, we used the chi-square test, Student t-test, and analysis of variance to identify factors related to long-term pain and fatigue with p < 0.1. These factors were then analyzed using logistic regression analysis. A p-value less than 0.05 was considered to indicate statistical significance.

Ethical Approval and Ministry Permission
We received approval for this study from the Afyonkarahisar Health Sciences University, Clinical Research Ethics Committee (January 8, 2021; Protocol 2021/57), as well as permission from the Ministry of Health of the Republic of Turkey. The ClinicalTrials.gov identifier number for the study is NCT04454333. The study was conducted following the principles of the Declaration of Helsinki. Written informed consent for the study was obtained.

Results
The patients’ demographic data, comorbidities, initial symptoms, pain sites, drugs used, and vaccination status are presented in Table 1. The frequencies of pain, severe fatigue, anxiety, and depression are shown in Figure 2.

The mean VAS, FSS, HADS-anxiety, HADS-depression, and SF-12 scores for female and male patients at their initial, 1-month, and 3-month follow-up evaluations are given in Table 2. The VAS score was higher in females than in males in both the 1-month and 3-month follow-ups (p = 0.040, p = 0.007, respectively). The mean VAS, FSS, HADS-anxiety, HADS-depression, and SF-12 scores showed statistically significant changes at 1 month and 3 months, respectively (Table 2).

There were no differences in pain severity, fatigue, anxiety, or depression according to disease severity (p > 0.05). When males and females were examined separately, the 3-month VAS value in the moderate disease category was significantly higher in females than in males (p = 0.009). In patients with severe disease, anxiety and depression scores were significantly higher in females than in males at the 3-month follow-up (p = 0.038, p = 0.010, respectively) (Table 3).
In the initial evaluations, VAS values and fatigue levels showed a moderately positive correlation ($p < 0.001$, $r = 0.38$).

In the long-term follow-up at 3 months, the correlation continued ($p < 0.001$, $r = 0.35$).

A weak correlation was found between the severity of depression symptoms and the VAS scores ($p = 0.007$, $r = 0.27$).

In the long-term (3-month) follow-up, the correlation was not maintained ($p = 0.058$).

In the evaluations done at hospital admission and at 3 months, moderately positive correlations between fatigue and depression symptoms ($p < 0.001$; $r = 0.52$, $r = 0.35$, respectively) and between fatigue and anxiety symptoms ($p < 0.001$; $r = 0.61$, $r = 0.44$, respectively) were detected.

SF-12 scores were negatively and weakly correlated with VAS scores at 3 months ($p < 0.001$, $r = 0.261$). SF-12 scores showed moderately negative correlations with fatigue ($r = 0.607$), depression ($r = 0.538$), and anxiety ($r = 0.564$) at 3 months.

Comparisons of age; sex; presence of comorbidities; and VAS, FSS, HADS-anxiety, and HADS-depression scores in patients with and without pain in the third month are shown in Table 4. Sex ($p = 0.018$), initial VAS values ($p < 0.001$), HADS-depression scores at 3 months ($p = 0.002$), and FSS scores at 3 months ($p < 0.001$) were statistically different between the patients with and without pain at 3 months (Table 4). Next, we analyzed sex, initial VAS values, HADS-depression scores (3-month), and FSS scores (3-month) using logistic regression analysis and found that high VAS values at hospital admission were predictive of pain in the 3-month follow-up (odds ratio [OR], 1.067; $p < 0.001$) (Table 5).

Comparisons of age, sex, and presence of comorbidities, as well as VAS, FSS, HADS-anxiety, and HADS-depression scores...
Arthralgia and myalgia are not unique to COVID-19 and are common symptoms of flu-like syndromes [15]. Myalgia is seen in up to 50% of COVID-19 patients [16]. We found the frequency of pain to be 46% in hospitalized COVID-19 patients. In a Turkish study, the most common pain symptoms were myalgia and arthralgia (69.2%) [17]. In another study, 159 patients reported at least 1 type of pain syndrome, with a prevalence of 71.6% [18]. Hoong et al. [19] reported that 30% of 294 hospitalized COVID-19 patients reported musculoskeletal symptoms. Of these, 88 patients (37.5%) had myalgia, 57% had arthralgia, 6.8% had new-onset back pain, and 50% had diffuse body pain. In our study, a detailed pain examination was conducted according to regions of the body, and back pain was found to be the most prevalent site (77%). This was followed by lower extremity pain (68%), neck pain (66%), upper extremity pain (64%), and low back pain (55%).

In a study of 379 patients in our hospital, the frequency of myalgia was found to be higher among patients in the ICU than on the ward [20]. Studies have reported that the frequency of pain increases as the severity of the disease increases. For example, in one study, low lymphocyte and high D-dimer levels, the presence of back pain, computed tomography findings of COVID-19, longer hospital stays, and chronic disease were associated with post-COVID-19 musculoskeletal symptoms [21]. Disser et al. [16] concluded that myalgia could be a predictive factor in determining overall disease severity in patients with abnormal chest computed tomography and radiography findings. Furthermore, Tuzun et al. [22] reported a higher incidence of arthralgia in patients with severe COVID-19, whereas Hoong et al. [19] concluded that the presence of musculoskeletal symptoms was not related to the risk of developing pneumonia. In our study, there were no significant differences in VAS scores according to disease severity. As far as we know, our study is the first to evaluate the presence and severity of pain in COVID-19 patients using the VAS. Unlike other studies, our study investigated whether the severity of pain, rather than the subjective presence of pain, changed according to the severity of the disease. Pain severity did not differ significantly between groups based on disease severity. Myalgia is a common symptom in COVID-19.

## Discussion

in patients with and without pain in the third month are given in Table 6. VAS (3-month, \( p = 0.001 \)), HADS-anxiety (3-month, \( p < 0.001 \)), and HADS-depression (3-month, \( p < 0.001 \)) scores showed a statistically significant difference between patients with and without severe fatigue in the third month. We then analyzed VAS (3 months), HADS-anxiety (3 months), and HADS-depression (3 months) scores using logistic regression analysis and found that high VAS scores (OR, 1.072; \( p = 0.003 \)) and anxiety levels (OR, 1.360; \( p = 0.007 \)) were predictive of severe fatigue in the third month (Table 7).

VAS, visual analog scale for measuring pain; FSS, fatigue severity scale; HADS, hospital anxiety depression scale; SF-12, short form-12; p, significance level of data between mild, moderate and severe disease groups without distinction between male and female.

*p*Significance level of the comparison of the mean of male and female within the group; **p** significance value of the difference between the mean age of patients with mild and moderate disease; "*p"significance value of the difference between the mean age of patients with mild and severe disease; "*p"significance value of the difference between the mean age of patients with moderate and severe disease; "*p"There was no difference between groups in post hoc analyses.

anxiety, and depression were reported in female patients [25]. In our study, we also found that the severity of pain was higher in females, although anxiety and fatigue were similar in both sexes. Understanding why pain is more common and more severe in females requires further research.

Although we found that pain persisted, it decreased from an initial rate of 46% to 27% at the 3-month follow-up. It has been reported in the literature that symptoms of COVID-19 can persist for up to 35 days and that approximately 10% of those infected with COVID-19 will suffer from musculoskeletal symptoms for some time within the first year [26,27]. The study by Karaarslan et al. [23] showed that approximately 2 out of 5 patients had at least 1 musculoskeletal symptom at 6 months. Fatigue, arthralgia, and myalgia are the most common musculoskeletal symptoms, both acutely and long-term.

https://doi.org/10.24171/j.phrp.2022.0275

45
Fatigue, muscle weakness, shortness of breath, pain and discomfort, anxiety and depression, and impaired concentration have been shown to persist in more than 20% of patients with post-COVID syndrome, up to 47% in some studies [28]. In one systematic review the prevalence of post-COVID syndrome reached 80% and symptoms, particularly fatigue, persisted for up to 24 weeks [29]. According to a large Chinese longitudinal cohort study, most COVID-19 survivors had a significant improvement at the 1-year follow-up. Although improved, these patients still had more problems with movement, pain, anxiety, or depression than the control group [30].

Research to optimize the management of post-COVID syndrome, the long-lasting symptoms of COVID-19 and their influencing factors, is ongoing. In the current literature, post-COVID syndrome is independent of the acute disease severity and the humoral response [31,32]. However, there are also studies showing that severe acute COVID-19, hospitalization, and comorbidities affect the persistence of symptoms [28], and that myalgia in the initial phase is associated with musculoskeletal pain as a post-COVID sequela [27]. Supporting this hypothesis, we found that high initial VAS scores were associated with pain at the 3-month follow-up. However, post-COVID syndrome is still poorly understood, and more research is needed [32].

There are studies showing that muscle weakness and decreased physical performance after COVID-19 infection [33] and chronic fatigue syndrome are common with COVID-19 [34,35]. In our study, we determined the frequency of severe fatigue, as evaluated with the FSS, to be 89% in hospitalized COVID-19 patients. Similarly, fatigue was reported in 85% of cases in a case series of 7 acute-phase patients [36]. In the study by Tuzun et al. [22], the most common musculoskeletal symptom was fatigue (85.3%). The overall prevalence of fatigue symptoms in one review was 25.6% (range, 4%¬100%) [5]. Goertz et al. [37] found that 92.9% and 93.5% of hospitalized and non-hospitalized COVID-19 patients, respectively, reported continued fatigue up to 79 days after disease onset. In a group of 120 hospitalized COVID-19 patients studied by Garrigues et al. [7], symptoms such as fatigue and shortness of breath were still present 110 days after the patients were sent home [7].

Because fatigue is a common and persistent symptom of COVID-19, it is important to analyze the associated factors. In a study by Townsend et al. [38], there was no relationship between the severity of the disease (hospital admission,

However, there are also studies showing that severe acute COVID-19, hospitalization, and comorbidities affect the persistence of symptoms [28], and that myalgia in the initial phase is associated with musculoskeletal pain as a post-COVID sequela [27]. Supporting this hypothesis, we found that high initial VAS scores were associated with pain at the 3-month follow-up. However, post-COVID syndrome is still poorly understood, and more research is needed [32].

There are studies showing that muscle weakness and decreased physical performance after COVID-19 infection [33] and chronic fatigue syndrome are common with COVID-19 [34,35]. In our study, we determined the frequency of severe fatigue, as evaluated with the FSS, to be 89% in hospitalized COVID-19 patients. Similarly, fatigue was reported in 85% of cases in a case series of 7 acute-phase patients [36]. In the study by Tuzun et al. [22], the most common musculoskeletal symptom was fatigue (85.3%). The overall prevalence of fatigue symptoms in one review was 25.6% (range, 4%¬100%) [5]. Goertz et al. [37] found that 92.9% and 93.5% of hospitalized and non-hospitalized COVID-19 patients, respectively, reported continued fatigue up to 79 days after disease onset. In a group of 120 hospitalized COVID-19 patients studied by Garrigues et al. [7], symptoms such as fatigue and shortness of breath were still present 110 days after the patients were sent home [7].

Because fatigue is a common and persistent symptom of COVID-19, it is important to analyze the associated factors. In a study by Townsend et al. [38], there was no relationship between the severity of the disease (hospital admission,

supplemental oxygen, or intensive care needs) and the severity of fatigue. This is supported by our study, which found that the severity of fatigue did not differ according to disease severity. Townsend et al. [38] also reported more fatigue in females than in males and in those previously diagnosed with depression and anxiety. A relationship between fatigue and anxiety has also been shown in different diseases, such as stroke [39]. We found that fatigue was correlated with pain, depression, and anxiety. The current literature suggests that pain and anxiety may be associated with fatigue in COVID-19 disease. Therefore, although fatigue was a persistent symptom in COVID-19 regardless of disease severity, it may be associated with female sex, anxiety, depression, and pain.

Depression, anxiety, and post-traumatic stress syndrome are all long-term sequelae of COVID-19 [34]. Ma et al. [40] reported a 43.1% prevalence of depression in COVID-19 patients, and that having a family member infected with COVID-19, having a severe COVID-19 infection, being male, and frequently using social media to obtain information about COVID-19 may be independently associated with depression. Cohorts with >20% of patients admitted to the ICU during acute COVID-19 outbreaks reported a higher prevalence of fatigue, anxiety, depression, and sleep disturbance than cohorts with ICU admissions <20% [41]. The reported risk factors for mental health symptoms include female sex and being a healthcare worker. While pain can be a risk factor for mental health symptoms, some studies have also reported no relationship between pain and anxiety or depression [10,42]. Initially, 47% of our patients had symptoms of anxiety and 73% had symptoms of depression. The proportion of patients with anxiety decreased to 9% at the 1-month follow-up and to 6% at the 3-month follow-up. Patients with symptoms of depression decreased to 17% and 12% at the 1-month and 3-month follow-ups, respectively. In our study, no significant differences were observed in the symptoms of anxiety or depression according to disease severity and sex. Only fatigue and symptoms of anxiety or depression were correlated. Although various risk factors for anxiety and depression after COVID-19 have been reported, studies with larger samples are needed on this subject.

Pain, fatigue, anxiety, and depression can significantly affect quality of life. Patients with COVID-19 have been reported to have a poor quality of life and suffer from significant physical and psychological impairments. Therefore, we need to follow up with patients to fully understand the long-term impact of COVID-19 and establish prompt and efficient interventions to mitigate its consequences [43]. In our study, we evaluated the quality of life for COVID-19 patients using the SF-36 questionnaire. The results showed that patients had lower scores in all domains compared to the general population, indicating a significant impact on their quality of life. However, we did not find any significant differences in the quality of life according to disease severity or sex.

COVID-19, coronavirus disease 2019; OR, odds ratio; CI, confidence interval; VAS, visual analog scale for measuring pain; HADS, hospital anxiety depression scale.
of life at 1 month and 3 months after discharge from the hospital and found a significant improvement in the quality of life at 3 months. It was an expected result that the quality of life would improve as the disease improved. Although significant improvements were reported in patients’ quality of life, based on the patients’ degree of dyspnea at rest and during daily activities for 15 days after discharge from the hospital, the quality of life in COVID-19 patients was worse than the normal population at 4-week and 6-week follow-ups [43–45]. Longer follow-up studies have also shown an overall lower quality of life for up to 3 months [25]. One study reported that people with severe COVID-19 demonstrated a low quality of life at their 6-month follow-ups [46].

Studies have shown that decreased muscle performance, functional capacity, and dyspnea after COVID-19 infection can lead to increased disability and decreased quality of life [47]. In an analysis of 420 patients, it was reported that sex, age, education level, employment status, diabetes, heart failure, and ICU admission were important independent predictors of quality of life [48]. In another study, a relationship was found between age, sex, the severity of clinical subtypes, length of hospital stay, lung function parameters, and some subscales of the SF-36 quality of life questionnaire [43]. In a cohort study of 251 patients followed for 3 months, female sex and the need for intensive care were independently associated with worsening quality of life [49]. It has also been reported that the incidence of low quality of life is higher among patients with a history of ICU admission and fatigue [50]. Quality of life was also worse in patients with persistent pain [10]. In our study, although there was no significant difference in quality of life based on disease severity and sex, quality of life was found to be negatively correlated with the severity of fatigue, anxiety, and depression symptoms. Therefore, it is important that rehabilitation be implemented to ease pain and fatigue so that patients can live better lives.

Conclusion

Pain, fatigue, anxiety, and depression appear to be long-term sequelae of COVID-19 and can significantly affect patients’ quality of life. Regardless of disease severity, a high initial VAS level may be a risk factor for long-term pain. High VAS and anxiety levels were also found to be associated with long-term fatigue.

At the time of our study, the pandemic was waning due to effective vaccines. However, the problems of patients with long-term COVID-19 should not be ignored. To improve the quality of life for people who have had COVID-19, further studies are needed that focus on treatment and rehabilitation.

Limitations

A limitation of our study is that COVID-19 patients who were not hospitalized were not examined.

Notes

Ethics Approval

This study was approved by the Research Ethics Commission of the Afyonkarahisar Health Sciences University (2021/57) and was performed in accordance with the principles of the Declaration of Helsinki. All participants provided written informed consent, which was confirmed by the Research Ethics Commission of the Afyonkarahisar Health Sciences University.

Conflicts of Interest

The authors have no conflicts of interest to declare.

Funding

None.

ABSTRACT

Objectives: Inflammation has been proposed to be one of the main causes of musculoskeletal pain. Diet is a lifestyle factor that plays an important role in managing inflammation; thus, we assessed the inflammatory potential of diets using the empirical dietary inflammatory index (EDII) to investigate the relationship between diet and musculoskeletal pain.

Methods: This cross-sectional study included 212 elderly individuals who were selected from health centers in Tehran, Iran. Dietary intake was evaluated using a valid and reliable 147-item food frequency questionnaire. To measure the intensity of pain, a visual analogue scale was used. Multiple linear regression was applied to assess the association between the EDII and musculoskeletal pain.

Results: In total, 62.7% and 37.3% of participants had mild and severe pain, respectively. The EDII values were 0.97 ± 0.72 and 1.10 ± 0.66, respectively, in those with mild and severe pain. A higher EDII score was associated with more intense musculoskeletal pain after adjusting for age and sex (β = 0.20; 95% confidence interval [CI], 0.06–0.26; p < 0.001), but not after adjustment for other confounders (β = –0.13; 95% CI, –1.54 to 0.60; p = 0.39).

Conclusion: Our findings indicated that higher dietary inflammation might not be associated with musculoskeletal pain in older adults. However, further investigations are required to confirm these findings.

Keywords: Aged; Empirical dietary inflammatory index; Inflammation; Musculoskeletal pain

Introduction

Musculoskeletal conditions affect the soft tissues, joints, and bones, are common in the elderly
Dietary inflammatory index and musculoskeletal pain

[1,2], and could lead to pain, a weakened locomotor system, and disability [3,4]. These conditions could also impose a heavy economic burden on society [5]. Although the exact mechanism is still not fully understood, evidence abounds showing that inflammation is present in those with inflammatory diseases such as rheumatoid arthritis and osteoarthritis [6]. It has been shown that an excessive amount of reactive oxygen species is present in individuals experiencing musculoskeletal conditions [7], along with other inflammatory markers such as tumor necrosis factor-alpha and interleukin-6 [8]. Therefore, it is reasonable to assume that managing inflammation could be an important step in mitigating musculoskeletal conditions [9]. Chronic inflammation can be significantly tackled by making lifestyle changes such as dietary interventions [10,11].

Some dietary components such as fruits, vegetables, whole grains, and spices, have been shown to demonstrate anti-inflammatory effects due to their high antioxidant and polyphenol content [12]. Conversely, high consumption of animal proteins and fats has been associated with increased inflammation [13,14]. However, due to the synergistic or antagonistic effects that foods have on each other, evaluating the overall dietary pattern could provide more comprehensive insights into the diet-disease association [15]. The empirical dietary inflammatory index (EDII) can be used for this purpose [16]. The EDII is a hypothesis-driven index that has been recently proposed to assess the potential pro- or anti-inflammatory effect of the diet based on the intake of various food groups [17]. Several studies have investigated associations between the EDII and chronic diseases and have shown that a higher EDII was associated with an increased risk of diabetes, metabolic syndrome, and fatty liver disease [18,19]. However, to our knowledge, the association of this dietary index with musculoskeletal pain has not been investigated yet. Given the importance of improving the quality of life in the elderly, we conducted this study to determine whether there is an association between musculoskeletal pain and the EDII in the elderly.

Materials and Methods

Study Design

This cross-sectional study was conducted among a total of 213 elderly individuals who were enrolled in our study from September 2019 to August 2020 at health centers in Tehran, Iran. We divided the city of Tehran into 5 regions (north, south, east, west, and center). Then, 20 health centers that individuals attended routinely for check-ups were selected. We tried to enroll a certain amount of people from each region to attenuate the likelihood of financial gaps among our participants. The sample size was determined employing the following formula: $N = \left[ \frac{(Z_1 - \alpha/2)^2 \cdot P(1-P)}{d^2} \right]$, using $P = 0.29$, $d = 0.06$, and $\alpha = 0.05$ [20]. The main inclusion criterion was being elderly ($\geq 60$ years old). The remaining inclusion criteria were as follows: having a history of musculoskeletal pain for at least 2 months, having no change in the usual dietary pattern over the previous year, being able to ambulate, not having a history of trauma or injury-related accidents, and not having cancer, acute diseases, and cognitive impairment. Participants following a special diet or those whose energy intake fell outside the normal range of 800 to 4,200 kcal were excluded from our study.

Participants’ Characteristics

After the first screening, some participants did not meet our inclusion criteria, missed the first interview, or declined to participate; eventually, 212 older adults were enrolled in the study. Socio-demographic data, including age, sex, marital status, economic status (very bad, bad, average, good, and very good) [21], educational level (up to diploma and upper diploma), exercise, sleep duration, supplement intake, history of diseases (cardiovascular diseases, diabetes, digestive diseases, psychological diseases, and skeletal disorders) and medication use, were gathered by trained researchers.

Dietary Assessment

Participants’ usual dietary intake was evaluated using a validated and reliable 147-item semi-quantitative food frequency questionnaire (FFQ) that elicited information on diet during the past 12 months on a daily, weekly, and monthly basis [22]. An expert nutritionist gathered dietary data through face-to-face interviews and converted portion sizes to intake (in grams) of each food item and nutrient. The Nutritionist IV software (First Databank Division, the Hearst Corporation; modified for Iranian foods) was used.

EDII scores were calculated based on dietary data derived from the FFQ, which has been used in previous studies [17,23]. The EDII includes 18 food groups. However, due to religious considerations, beer and wine were not included in the dietary score. Moreover, high- and low-energy beverages were considered a single food item in the FFQ. Therefore, we calculated the EDII score based on 15 food groups and 2 categorizations of inflammatory potential. The anti-inflammatory food group consisted of tea, coffee, dark yellow vegetables, leafy green vegetables, snacks, fruit juice, and pizza. Meanwhile, the pro-inflammatory group includes processed meat, red meat, organ meat, other fish (fish, or canned tuna), other vegetables (mixed vegetables, cooked mushrooms, green peppers, zucchini, eggplant, or cucumbers), refined grains, high-energy and low-energy beverages...
drinks, and tomatoes. Regression coefficients were used to weigh the mean daily intake of the food groups. The obtained values were then summed and divided by 1,000. Positive scores of the EDII are an index of pro-inflammatory diets, while negative scores correspond to anti-inflammatory diets.

Pain Evaluation
A visual analogue scale, a valid, reliable, and responsive tool [24] with 0 to 10-cm lines, was used to measure the pain intensity of participants during the previous 3 months. Its score ranges from 0 to 10, with 0 indicating no pain, < 3 denoting mild pain, and ≥ 3 corresponding to severe pain [25]. Participants were asked to draw a vertical mark on the lines to indicate their pain level.

Assessment of Other Variables
Anthropometric measurements (height, body weight, body mass index [BMI], waist circumference [WC], and hip circumference) were assessed for all participants. Height was measured in the standing shoeless position by a standard stadiometer to the nearest 0.1 cm. Body weight was assessed by a digital scale (SECA) to the nearest 0.1 kg while participants wore light clothing. BMI was calculated as weight divided by height squared (kg/m²) [26]. WC was assessed with an accuracy of 0.1 cm, at the level of the iliac crest [27], and hip circumference was recorded at the anterior superior iliac spine level [26]. Physical activity was evaluated by asking participants about their daily average time spent jogging, exercising, or engaging in other sports. The activity level was ranked into 4 categories (light, moderate, strong, and intense). Participants’ physical activity level was calculated as metabolic equivalent-hours/day [28].

Statistical Analysis
The characteristics of the study population are expressed as mean ± standard deviation (for normally distributed data) or median (for data with a skewed distribution). The normality of the distribution of variables was assessed using the Kolmogorov-Smirnov test. The independent sample t-test and the chi-square test were used to evaluate the qualitative and quantitative variables, respectively.

The dietary intake of study participants across animal and plant protein tertiles was compared using analysis of covariance. All values were adjusted for energy intake. We used multiple linear regression analysis to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for musculoskeletal pain across EDII tertiles in crude and multivariable-adjusted models. Age, sex, education, economic status, physical activity, BMI, energy intake, and economic status were adjusted in the control model. IBM SPSS ver. 24.0 (IBM Corp.) was used to perform the statistical analysis. A p-value < 0.05 was considered to indicate statistical significance.

Ethics Statement
All patients were informed about the characteristics of the study and signed a written informed consent form. The study protocol was reviewed and approved by the local ethical committee of Islamic Azad University, Tehran, Iran (Code: 1397174.IR.IAU.SRB.REC).

Results
The demographics, lifestyle, work-related, and health characteristics of the participants are described in Tables 1 and 2, according to the intensity of pain. We evaluated 212 participants, of whom 48 were men (22.6%) and 164 were women (77.4%), with an average age of 66 years. The pain assessment showed that 62.7% and 37.3% of the participants experienced mild and severe pain, respectively. The BMI was 28.43 ± 3.76 kg/m² and 29.15 ± 4.22 kg/m² in those with mild and severe pain, respectively. The EDII values were 0.97 ± 0.72 and 1.10 ± 0.66 in participants with mild and severe pain, respectively; this difference was not statistically significant. Furthermore, 67.5% and 32.5% of participants with mild and severe pain were married. A comparison between the 2 pain groups indicated remarkable differences between them in terms of the head of the family, educational level, economic status, and psychological disorders (p = 0.01, p = 0.001, p = 0.001, p = 0.004, and p = 0.003, respectively). Additionally, gastrointestinal, cardiovascular, and psychological medication intake, and vitamin D supplement usage were significantly different between the mild and severe pain groups (p = 0.01, p = 0.02, p = 0.002, and p = 0.03, respectively).

The dietary intake of participants by tertile of EDII scores is presented in Table 3. People in the third tertile of the EDII consumed higher amounts of total energy, protein, total fat, saturated fat, monounsaturated fat, polyunsaturated fat, fiber, processed meat, red meat, other fish, other vegetables, refined grains, and tomatoes (p < 0.05). The intake of other dietary components such as carbohydrates, tea, coffee, dark yellow vegetables, leafy green vegetables, snacks, fruit juice, pizza, organ meat, and beverages did not differ according to the tertile of the EDII score.

Table 4 demonstrates the association between the EDII and musculoskeletal pain shown by multiple linear regression (Table 5). In the crude model, the EDII did not have a significant association with musculoskeletal pain (β = 0.07; 95% CI, −1.40 to 4.17; p = 0.32). After adjusting for covariates including age and sex, the association became significant (β = 0.20; 95% CI, 0.06–0.26; p < 0.001). However, the fully

Discussion

The present study investigated the association between the EDII and musculoskeletal pain in older adults. A higher EDII was significantly associated with differences in nutrient and food intake. Furthermore, there was a significant positive association between EDII and musculoskeletal pain after adjusting for age and sex.

Our study showed a significant association between the EDII and intake of total energy, protein, total fat, saturated fat, monounsaturated fat, polyunsaturated fat, fiber, processed meat, red meat, other fish and vegetables, refined grains, and tomatoes. As Phillips et al. [29] indicated in their study, the consumption of red and processed meats and refined cereals/grains was higher and the intake of whole grains, fish,

and low-fat dairy products was lower in participants with higher pro-inflammatory scores. Similarly, Bagheri et al. [30] reported that there was a significant association between the food-based inflammatory potential of the diet and greater consumption of refined grains, red meats, high-fat dairy, soft drinks, and potatoes. In addition, different fatty acids can stimulate inflammatory processes, or anti-inflammatory cell function through various mechanisms [31]. For instance, although monounsaturated and polyunsaturated fatty acids have anti-inflammatory properties, the n-6/n-3 ratio has been shown to be associated with the inflammatory response and coagulation [32]. Since the relationship between chronic conditions and inflammation is widely recognized, it is important to pay attention to the content and the inflammation score of individuals’ diets.

Our findings showed no direct association between the EDII and musculoskeletal pain. Although studies on this topic are limited, Enrico [33] examined the relationship between the DII and chronic pain in adults, and the results showed that dietary inflammatory index (DII) scores were significantly related to the presence of neck and back pain. In addition, DII scores have been associated with pain lasting longer than 24 hours and 3 months. Similarly, Toopchizadeh et al. [34] revealed that the DII score was directly linked to pain intensity in knee osteoarthritis patients, and a higher DII score was associated with higher odds of having severe pain. In contrast, Correa-Rodriguez et al. [35] reported no association between the DII score and clinical symptoms in women with fibromyalgia. Nevertheless, they found that the DII score was associated with lower pressure pain thresholds.

Various studies have emphasized the anti-inflammatory properties of foods, which have been reported to reduce chronic pain, osteoarthritis-related pain, and neurogenic pain [36–38]. Anti-inflammatory diets can reduce pain via several putative mechanisms. Anti-inflammatory components such as flavonoids, curcuminoids, omega-3 polyunsaturated fatty acids, trombone, and taurine could have analgesic effects by preventing inflammatory signaling, regulating cyclooxygenase 2 activity, interacting with neuromodulator pathways (including the opiate receptors and the gamma-aminobutyric acid receptor signaling), targeting L-arginine/nitric oxide signaling, and reducing the production of prostaglandin E2 [37,39–41].

Although the present study was relatively novel and could further expand our knowledge of the detrimental effects of

a pro-inflammatory diet, there are some limitations that should be considered. Firstly, because of the cross-sectional nature of the study, we could not infer causality. Another limitation was the small sample size. Moreover, when using an FFQ, the risk of recall bias is substantial. Additionally, since our study population only included the elderly, our results cannot be extended to other populations. Finally, due to financial constraints, we were unable to assess inflammatory blood markers, although doing so could have provided better insights into this topic.

Conclusion

In conclusion, our findings indicated no association between a higher EDII and musculoskeletal pain in older adults. However, further investigations with a larger sample size, longitudinal and interventional design, and different populations are required to deepen our knowledge of the association between dietary indices and musculoskeletal pain.

Notes

Ethics Approval
All patients were informed about the characteristics of the study and signed a written informed consent form. The study protocol was reviewed and approved by the local ethical committee of Islamic Azad University, Tehran, Iran (Code: 1397.174.IR.IAU.SRB.REC).

Conflicts of Interest
The authors have no conflicts of interest to declare.

Funding
None.

Availability of Data
All data generated or analyzed during this study are included in this published article. Other data may be requested from the corresponding author.

ABSTRACT

Objectives: The coronavirus disease 2019 (COVID-19) pandemic has continued since its first detection in the Republic of Korea on January 20, 2020. This study describes the early countermeasures used to minimize the risk of COVID-19 outbreaks during cohort quarantine and compares the epidemiological characteristics of 2 outbreaks in long-term care facilities (LTCFs) in Gwangju Metropolitan City in summer 2020.

Methods: An epidemiological investigation was conducted via direct visits. We investigated epidemiological characteristics, including incidence, morbidity, and mortality rates, for all residents and staff members. Demographic characteristics were analyzed using a statistical program. Additionally, the method of managing infection in LTCFs is described.

Results: Residents and caregivers had high incidence rates in LTCF-A and LTCF-B, respectively. LTCF-B had a longer quarantine period than LTCF-A. The attack rate was 20.02% in LTCF-A and 27.9% in LTCF-B. The mortality rate was 2.3% (1/43) in LTCF-B, the only facility in which a COVID-19 death occurred.

Conclusion: Extensive management requires contact minimization, which involves testing all contacts to mitigate further transmission in the early stages of LTCF outbreaks. The findings of this study can help inform and prepare public health authorities for COVID-19 outbreaks, particularly for early control in vulnerable facilities.

Keywords: Cohort isolation; COVID-19; Long-term care facility

Introduction

Since the first case of coronavirus disease 2019 (COVID-19), which is caused by severe acute...
respiratory syndrome coronavirus 2 (SARS-CoV-2), was confirmed in the Republic of Korea (ROK) on January 20, 2020, the disease has been identified in diverse sites in cluster patterns. Moreover, SARS-CoV-2 infection can manifest as a respiratory disease with severe pneumonia-like symptoms that require critical care [1]. The elderly population is generally susceptible, with a high incidence of severe disease and mortality. Those who attend gatherings face a high risk of infection and risk of complications. Deaths related to COVID-19 have been reported in other countries [2–4]. Eighty percent of deaths associated with COVID-19 were among adults aged ≥65 years, with the highest percentage of severe outcomes among persons aged ≥85 years [5]. Mortality was reported most commonly among individuals aged ≥80 years [6].

According to the Korea Disease Control and Prevention Agency (KDCA), as of July 1, 2020, deaths in the ROK due to COVID-19 totaled 282 cases of 1,285,231 individuals tested, with a mortality rate of 2.1%. The total number of cases in Gwangju Metropolitan City was 56 [7]. COVID-19 outbreaks have resulted from a variety of gatherings, including in churches and temples. The first long-term care facility (LTCF) outbreak and resident death occurred in Gwangju Metropolitan City. There have been no prior reports on early countermeasures for cluster LTCF outbreaks. This study describes the epidemiological characteristics and efforts to mitigate the spread of COVID-19 in LTCFs. It compares 2 LTCFs’ extensive public health responses to COVID-19 outbreaks in order to assess similarities and differences in disease spread and individuals affected.

Materials and Methods

Epidemiological Investigation

Based on the Infectious Disease Control and Prevention Act, we identified and investigated patients as relevant who had worked at and been infected at LTCF-A and LTCF-B, and their contacts between June 26, 2020 and July 30, 2020 [8]. A confirmed person was defined as someone with laboratory-confirmed COVID-19 infection, regardless of clinical signs and symptoms [9,10], and the index case was defined as the first confirmed case of SARS-CoV-2 infection within a cluster outbreak. After epidemiological investigation to confirm the route of transmission, origin, and exposure environment, patients with COVID-19 were given appropriate medical care. We obtained information on demographic characteristics from interviews using standardized epidemiological investigation forms. For supplemental measures to trace contacts, we obtained additional personal epidemiological information using the global positioning system (GPS), credit card transactions, drug utilization review, and closed-circuit television.

Outbreak Recognition and Response Measures

We were alerted to the index cases of COVID-19 as caregivers who worked in LTCF-A and LTCF-B. The first confirmed case included another cluster associated with suspected acute respiratory illness.

The KDCA’s immediate response team was sent to the spot for epidemiological investigation with contact tracing. Countermeasure response teams were launched immediately, namely the Gwangju Center for Infectious Disease Control and Prevention, Gwangju Infectious Disease Response Team, and Gwangju Buk-gu Public Health Center. The investigative response identified an outbreak during the cohort isolation group’s quarantine period in LTCF-A and LTCF-B in Gwangju Metropolitan City, during a COVID-19 mass screening of residents (n = 52) and staff members (n = 31).

After the index case was identified, movement within LTCF-A and LTCF-B was limited. Visitors were prohibited from entering the facilities in order to limit exposure, since interaction had the potential for disease transmission. Each resident was assigned to a single room or a room with divided partitions, and no group activities were allowed. To prevent additional transmission, personal protective equipment (PPE) for staff members was always worn when caring for residents. Fever and symptoms such as cough, myalgia, and headaches were monitored and recorded daily. Nasopharyngeal swab specimens from all residents and staff, including caregivers, were screened using real-time reverse-transcription polymerase chain reaction (RT-PCR). All residents and staff were isolated for testing every 3 days and quarantined for 14 days after a positive result was confirmed. Those who were confirmed positive were transferred to other hospitals or treatment centers in the community. A person who had a negative test result after contact with a confirmed case was mandated to remain quarantined at the facility for 14 days.

Enhanced hygiene measures were implemented, including disinfection of surfaces and periodic natural ventilation through windows. In addition, after the contaminated room or area was cleaned, environmental sampling was performed. Environmental testing for SARS-CoV-2 at LTCF-A and LTCF-B was performed on July 1, 2020 and July 9, 2020, respectively.

Ethics Statement

Ethics approval was waived for this study because it was considered part of a response to a public health crisis.
Results

LTCF-A is a 2-story structure located near a residential area. Twenty-six residents were managed by 14 staff members between June 26, 2020 and July 30, 2020. Resident space was located on the first and second floors of the building. The space was utilized by placing 2 persons per room. An elevator was used to move food and supplies, but not people, between floors. Ventilation was possible only by opening the window.

LTCF-B is a 4-story structure located in a rural area. Twenty-six residents were managed by 17 staff members. The space was utilized by placing 2 to 4 persons per room. Resident space was located on the first and second floors, and staff space was located on the third floor and the first basement floor of the building. Air conditioning and open windows were used for ventilation.

LTCF-A was quarantined immediately on July 1, 2020, after a caregiver on staff was identified on June 30 as the index case, and RT-PCR testing was performed on all personnel. As a result, 3 residents were confirmed to be positive and were transferred immediately to a hospital. As a complementary measure, all remaining personnel were quarantined for cohort isolation. On July 3, 3 asymptomatic residents were confirmed positive, after which no further positive results occurred until July 17, due to the 14-day quarantine.

Among the 26 residents of LTCF-A, all 6 positive cases were >70 years old (mean age, 81.5), and the 2 positive staff had a mean age of 43.5 years (Table 1). In LTCF-B, the average age of positive cases among residents was 87.6 years, and among staff was 56.4 years. More than 80% of the positive staff members showed initial symptoms such as fever, muscle pain, and fatigue. However, 100% (6/6) of the residents in LTCF-A and 71.4% (5/7) in LTCF-B were asymptomatic. Only 28.6% (2/7) of residents in LTCF-B showed symptoms, such as fever, muscle pain, sore throat, cough, and lethargy. Among the positive residents, 1 person died on July 16 from lethargy. The positive residents had comorbidities, including 11 with dementia (55%), 7 with hypertension (35%), 5 with diabetes (25%), and 3 with hyperlipidemia (n = 3). Five residents were able to ambulate in a wheelchair, and 1 had difficulty in communication and movement (data not shown).

As illustrated in Figure 1, the index case at LTCF-B (symptomatic date: June 29), confirmed subsequently as positive for SARS-CoV-2, was already a patient under investigation on July 1. The index case at LTCF-B met the index case of LTCF-A on June 27 based on GPS tracking (data not shown). All LTCF-B personnel were evaluated and tested using RT-PCR.

</table>
as well. As a result of cumulative testing, on July 2, 2020, 4 people were confirmed positive for SARS-CoV-2, and the remaining personnel were isolated in single rooms on the second and third floors as a follow-up measure. Two people tested positive on July 5, 8, and July 10. Cohort isolation was sustained for 14 days after the last confirmed case. After the start of quarantine on July 1 in LTCF-B, staff in the basement oversaw floor 1 residents, and staff on floor 3 oversaw floor 2 residents. To prevent infection, staff members were required to wear
protective suits when entering the room. Movement between floors outside of each person’s living area was prohibited for disease control. The secondary attack rate was 8.3% (1/12), as close contacts with the first index case mingled among household members associated with LTCF-A.

For environmental evaluation, on July 1, LTCF-A collected 31 samples from patients’ contact places (door handles, toilet handles, toilet bowls, etc.). As indicated by RT-PCR, only the handle of the front door was confirmed to be positive for SARS-CoV-2. The exposure site was sterilized 1 hour before sampling; however, the entrance door handle was not sterilized because the front door was open. Cycle threshold values for the E gene and RdRp gene of the door handle were 33.25 and 35.07, respectively. On July 9, 25 samples were collected from major contact places, including air purifiers and ventilation systems in LTCF-B. All of these RT-PCR test results were negative.

As a result of the epidemiological investigation associated with contact tracing, the expected transmission is shown in Figure 2. The first transmission was initiated by a meeting between the index cases of LTCF-A and LTCF-B. Transmission within LTCF-A was caused by only 1 staff member; transmission in LTCF-B started from the staff of LTCF-A, and additional transmission was caused by each facility’s workers.

Discussion

This report has shown that countermeasures to COVID-19 outbreaks among the elderly who have greater risk of developing a more severe form of the disease. Strategy measures for COVID-19 among the elderly were followed by comprehensive tracing of all identified contacts. The extensive public health response to support LTCF residents included active testing to ascertain a mass screening for case detection and mitigate the risk of SARS-CoV-2 infection, quarantine of all contacts, and treatment of confirmed cases.

A previous study indicated that most elderly people residing in LTCFs have a significantly higher risk of severe disease and death [11]. Numerous deaths due to SARS-CoV-2 in LTCFs have been reported in other countries [12–14]. Previous studies have reported that most facilities requiring nursing had a significantly higher risk of severe disease and death, and it was estimated that approximately 42% of deaths were associated with COVID-19 [12]. In this study, the mortality rate was 8.33% (1/12) in LTCF-B. We found that the mortality rate was lower than previous findings, which ranged between 20.8% and 28.0% in similar populations [15,16]. This result indicates that the attack rate (incidence rate) was 20.02% and 27.9% in LTCF-A and LTCF-B, respectively. The morbidity rates were 5.0% (2/40) in LTCF-A and 14.0% (6/43) in LTCF-B. The mortality rate may be higher among those with pre-existing comorbidities, particularly cardiovascular disease, diabetes, chronic respiratory disease, hypertension, and cancer [17].

This study showed a high prevalence of asymptomatic infections among infected older residents, and of those who tested positive, only staff members exhibited symptoms. Viral shedding may peak in the pre-symptomatic phase within the primary stage of infection [18]. Most residents had a high risk due to the presence of multiple comorbidities, such as diabetes, high blood pressure, and dementia. Almost all the residents who tested positive had underlying chronic medical conditions. Among the positive residents in both facilities, all from LTCF-A and 71.4% from LTCF-B had dementia, which was in accordance with the asymptomatic state. Furthermore, none of the staff members of LTCF-A and 20% of those in LTCF-B were asymptomatic.

This result differs from a report wherein 75% of nursing home staff were asymptomatic [19]. The quarantine periods were 20 days for LTCF-A and 32 days for LTCF-B. The countermeasures were the same; however, the quarantine periods were different. It is estimated that the asymptomatic rate among caregivers is high. Contagious symptomatic or asymptomatic carriers of SAR-CoV-2 could represent the leading cause of increased COVID-19 transmission [20].

Social gatherings may pose an increased risk of infection. Residents and workers share space and materials in nursing facilities. Residents had a high incidence rate in LTCF-A while caregivers had a higher incidence rate in LTCF-B. The total quarantine period was extended (17 days at LTCF-A and 29 days at LTCF-B) after confirming the last positive case. There was no additional transmission by positive residents in LTCF-A, whereas more transmission occurred among caregivers in LTCF-B. Physical interactions with personnel may result in an increase in infectious diseases [21]. Therefore, staff must be educated to mitigate transmission during the quarantine period.

There were concerns about worsening of symptoms due to inherent characteristics of the elderly, such as the presence of underlying diseases like dementia, that required management. More effort was required to mitigate the risk of SARS-CoV-2 infection among these vulnerable groups. Therefore, RT-PCR diagnostic testing was conducted every 3 days as a countermeasure for the possibility of worsening asymptomatic cases. This method focused on rapidly identifying and relocating confirmed cases from the cohort environment to decrease the frequency of SARS-CoV-2 infection in the facility. To reduce contact and exposure, each resident was assigned to a single or double room. It has been reported that the incidence and mortality doubled.
as density increased [22]. Team-based approaches, such as space separation, routine symptom monitoring of staff and residents, allocation of sufficient PPE, community support, and testing capacity, have been implemented to reduce additional infections. Similarly, other reports have shown reductions in incidence and mortality through preventive isolation (self-confinement) [23,24].

The current study has some limitations. Analysis of exposure risk was not possible because research, such as surveys on individual behavioral characteristics, could not be conducted. Although it is a report on the early countermeasures of an LTCF group outbreak in the early stages of the COVID-19 pandemic, the findings of this study can help inform and prepare public health authorities for COVID-19 outbreaks or other infectious disease outbreaks, particularly in setting up quarantine in vulnerable facilities. We hope that our records can be effectively utilized to mitigate SARS-CoV-2 transmission and protect vulnerable populations in LTCFs.

Notes

Ethics Approval
Ethics approval was waived for this study because it was considered part of a response to a public health crisis.

Conflicts of Interest
The authors have no conflicts of interest to declare.

Funding
This work was supported by funding from the Korea Disease Control and Prevention Agency (2020, 6231-335-210-01).

Availability of Data
All data generated or analyzed during this study are included in this published article. Other data may be requested through the corresponding author.

Authors’ Contributions
Investigation: HJK, JK, YSJ, HP, JMK, SYR, JHC, SYP. Project administration: JYP. Supervision: SEL. Writing–original draft: HJK. Writing–review & editing: all authors. All authors read and approved the final manuscript.

References

https://doi.org/10.24171/j.phrp.2022.0293
Osong Public Health and Research Perspectives (PHRP) is the international bimonthly (published at the end of February, April, June, August, October, and December) journal founded in 2010 by the Korea Disease Control and Prevention Agency (KDCA). With the mission of the KDCA, to create a disease-free world, PHRP encourages sharing medical information and knowledge in the areas of public health. PHRP publishes original articles, review articles, guidelines, data profiles (including cohort profiles), special articles, short communications, viewpoints, editorials and correspondence, with a focus on the following areas of expertise: emerging infectious diseases, vaccinology, zoonotic diseases, non-communicable diseases, intractable and rare diseases, and human genomics.

Before submitting a manuscript, authors should carefully read and follow the instructions for writing an article for PHRP. For issues not addressed in these instructions, authors should refer to the Recommendations for the Conduct, Reporting, Editing, and Publication of Scholarly Work in Medical Journals (http://www.icmje.org/recommendations/) from the International Committee of Medical Journal Editors (ICMJE). Manuscripts submitted to PHRP that do not follow these instructions will be returned to the authors without further review.

ARTICLE PROCESSING CHARGES
RESEARCH AND PUBLICATION ETHICS
EDITORIAL POLICY
SUBMISSION & PEER REVIEW PROCESS
MANUSCRIPT PREPARATION
FINAL PREPARATION FOR PUBLICATION

ARTICLE PROCESSING CHARGES

The author does not have pay publication charges for open access. The KDCA will pay to make the article open access.

RESEARCH AND PUBLICATION ETHICS

The journal adheres to the guidelines and best practices published by professional organizations, including the ICMJE Recommendations and the Principles of Transparency and Best Practice in Scholarly Publishing (joint statement by the Committee on Publication Ethics [COPE], Directory of Open Access Journals [DOAJ], World Association of Medical Editors [WAME], and Open Access Scholarly Publishers Association [OASPA]; https://doaj.org/bestpractice). Furthermore, all processes of handling research and publication misconduct shall follow the applicable COPE flowchart (https://publicationethics.org/resources/flowcharts).

Human and Animal Rights

Clinical research should be conducted in accordance with the World Medical Association’s Declaration of Helsinki (https://www.wma.net/what-we-do/medical-ethics/declaration-of-helsinki/) and approved by the Institutional Review Board (IRB) of the institution where the experiment was performed. Animal experiments should also be reviewed by an appropriate committee (Institutional Animal Care and Use Committee [IACUC]) for the care and use of animals. Studies involving pathogens requiring a high degree of biosafety should pass review of a relevant committee (Institutional Biosafety Committee [IBC]). Clinical studies that do not meet the Helsinki Declaration will not be considered for publication.

Statement of Informed Consent and Institutional Approval

The editor of PHRP may request submission of copies of informed consent forms from human subjects in all studies and IRB approval documents. Articles where human subjects can be identified in descriptions, photographs, or pedigrees must be accompanied by a signed statement of informed consent to publish (in print and online) the descriptions, photographs, and pedigrees of each subject who can be identified. Articles describing the use of human samples in research and human experiments must be approved by the relevant review committee. Articles describing the use of animals in experiments must be approved by the relevant authorities.
Originality

Manuscripts are considered with the understanding that no part of the work has been published previously in print or electronic format and the paper is not under consideration by another publication or electronic medium.

Secondary Publication

It is possible to republish manuscripts if the manuscripts satisfy the conditions for secondary publication as described in the ICMJE Recommendations (http://www.icmje.org/icmje-recommendations.pdf).

Plagiarism and Duplicate Publication

Attempting to publish substantially similar work more than once without attribution of the original source(s) is considered a redundant publication. The definition of “substantially similar” is as follows: (1) at least one of the authors is common to all reports (it is likely to be plagiarism if there are no common authors); (2) the subject or study populations are the same or similar; (3) the methodology is typically identical or nearly so and; (4) the results and interpretation vary little or not at all.

If all or part of the subject population has been reported previously, it should be declared in the Materials and Methods and must be appropriately referenced. In cases where authors are concerned with any potential overlap with published manuscripts or manuscripts being reviewed, the authors must include a letter explaining how the manuscript submitted to PHRP significantly differs from other materials. For more information, please refer to ICMJE Recommendation (available at: http://www.icmje.org/recommendations/).

Authorship and the Author’s Responsibilities

Authorship credit must be based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; (3) final approval of the version to be published; and (4) agreeing to be accountable for all aspects of the work in ensuring that the questions related to the accuracy or integrity of any part of the work are appropriately in vestigated and resolved. The authors should meet these 4 conditions. If the number of authors exceeds 3, the specific role(s) of authors should be described at the end of the main text.

- Correction of authorship: Any requests for changes in authorship (adding author(s), removing author(s), or re-arranging the order of authors) after the initial manuscript submission and before publication should be explained in writing to the editor in a letter or e-mail from all authors. This letter must be signed by all authors of the paper. A copyright assignment must be completed by every author.
- Role of the corresponding author: The corresponding author takes primary responsibility for communication with the journal during the manuscript submission, peer review, and publication process. The corresponding author typically ensures that all of the journal's administrative requirements, such as providing the details of authorship, ethics committee approval, clinical trial registration documentation, and conflict of interest forms and statements, are properly completed, although these duties may be delegated to one or more coauthors. The corresponding author should be available throughout the submission and peer review process to respond to editorial queries in a timely manner, and after publication, should be available to respond to critiques of the work and cooperate with any requests from the journal for data or additional information or questions about the article.
- Contributors: Any researcher who does not meet all 4 ICMJE criteria for authorship discussed above but contributes substantively to the study in terms of idea development, manuscript writing, conducting research, data analysis, and financial support should have their contributions listed in the Notes section of the article.
- Recommendations for working with people with personal connections: Authors who intend to include minors (under the age of 19) or their family members (such as spouse, children, and relatives) in their research, including when publishing or presenting papers jointly with them, should clearly indicate this in the cover letter. For further information, please refer to the “Guidelines for Preventing Illegitimate Authorship” by the National Research Foundation of Korea (https://www.cre.re.kr/).

Conflict of Interest Statement

The corresponding author must inform the editor of any potential conflicts of interest that could influence the authors’ interpretation of the data. Examples of potential conflicts of interest are financial support from or connections to companies, political pressure from interest groups, and academically related issues. In particular, all sources of funding applicable to the study should be explicitly stated.
Role of the Funding Source

The author is requested to identify who provided financial support for the conduct of the research and/or preparation of the article and to briefly describe the role of the sponsor(s), if any, in study design; in the collection, analysis and interpretation of data; in the writing of the report; and in the decision to submit the article for publication. If the funding source(s) had no such involvement, then this should be stated.

Process for Managing Research and Publication Misconduct

When the journal faces suspected cases of research and publication misconduct such as redundant (duplicate) publication, plagiarism, fraudulent or fabricated data, changes in authorship, an undisclosed conflict of interest, ethical problems with a submitted manuscript, a reviewer who has appropriated an author’s idea or data, complaints against editors, and so on, the resolution process will follow the flowchart provided by the COPE (http://publicationethics.org/resources/flowcharts). The editorial boards of PHRP will carry out the discussion and decision for suspected cases. We will not hesitate to publish errata, corrigenda, clarifications, retractions, and apologies when needed.

Complaints and Appeals Policy

The policies of PHRP are principally intended to protect the authors, reviewers, editors, and the publisher of the journal. The process of handling complaints and appeals follows the guidelines of the COPE (https://publicationethics.org/guidance/Guidelines).

Editorial Responsibilities

The Editorial Board will continuously work to monitor and safeguard publication ethics, including guidelines for retracting articles; maintenance of the integrity of the academic record; preclusion of business needs from compromising intellectual and ethical standards; publishing corrections, clarifications, retractions, and apologies when needed; and excluding plagiarism and fraudulent data. The editors maintain the following responsibilities: responsibility and authority to reject and accept articles; avoiding any conflict of interest with respect to articles they reject or accept; promoting publication of corrections or retractions when errors are found; and preservation of the anonymity of reviewers.

EDITORIAL POLICY

Copyright

The Korea Disease Control and Prevention Agency (publisher) holds the copyright on all submitted materials and the right to publish, transmit, sell, and distribute them in the journal or other media. The publisher applies the Creative Commons Attribution license to works it publishes. Under this license, although the publisher retains ownership of the copyright for content, it allows anyone to download, reuse, reprint, distribute, and/or copy the content for non-commercial purposes.

Open Access License

Every article appearing in this journal will be published as open-access. Articles are distributed under the terms of the Creative Commons Attribution-Non Commercial-No Derives (http://creativecommons.org/licenses/by-nc-nd/4.0/), which permits unrestricted non-commercial use, distribution, and reproduction in any medium, provided the original work is properly cited. Author(s) do not need to permission to use tables or figures published in PHRP in other journals, books, or media for scholarly and educational purposes.

Article Sharing (Author Self-Archiving) Policy

PHRP is an open access journal, and authors who submit manuscripts to PHRP can share their research in several ways, including on preprint servers, social media platforms, at conferences, and in educational materials, in accordance with our open access policy. However, it should be noted that submitting the same manuscript to multiple journals is strictly prohibited.

Data Sharing Policy

To foster transparency, we encourage authors to state the availability of their data in your submission. This may be a requirement of your funding body or institution. If the data are unavailable to access or unsuitable to post, authors will have the opportunity to indicate why during the submission process, for example by stating that the research data are confidential.

Archiving Policy

The full text of PHRP has been archived in PubMed Central (https://www.ncbi.nlm.nih.gov/pmc/journals/2151/) from the first volume, 2010. According to the deposit policy (self-archiving policy) of Sherpa/Romeo (http://www.sherpa.ac.uk/), authors cannot archive pre-prints (i.e., pre-refereeing), but they can archive post-print (i.e., final drafts post-refereeing). Authors can archive the publisher’s version/PDF. PHRP provides electronic backup and preservation of access to the journal content in the event the journal is no longer published by archiving the journal content in PubMed Central and the National Library of Korea.

Preprint Policy

A preprint can be defined as a version of a scholarly paper that precedes formal peer review and publication in a peer-reviewed scholarly journal. PHRP allows authors to submit the preprint to the journal. It is not treated as duplicate submission or duplicate publication. PHRP recommend authors to disclose it with DOI in the letter to the editor during the submission process. Otherwise, it may be screened from the plagiarism check program—Similarity Check (Crosscheck) or Copy Killer. Preprint submission will be processed through the same peer-review process with a usual submission. If the preprint is accepted for publication, authors are recommended to update the info at the preprint with a link to the published article in PHRP, including DOI at PHRP. It is strongly recommended that authors cite the article in PHRP instead of the preprint at their next submission to journals.

Peer Review Policy

All papers, including those invited by the editor, are subject to peer review. PHRP has adopted a double-blind peer review policy, where the author identities remain anonymous to the reviewers, and vice versa, and the identities of the reviewers and authors are visible to (decision-making) the editor throughout the peer review process. The Editorial Board selects reviewers based on expertise, publication history, and past reviews. During the peer review process, reviewers can interact directly or exchange information (e.g., via submission systems or email) with only an editor, which is known as “independent review.” An initial decision will normally be made within 4–6 weeks after the reviewers agree to review a manuscript. No information about the review process or editorial decision process is published on the article page.

Online Submission

All manuscripts should be submitted online at https://mc04.manuscriptcentral.com/osongphrp (PHRP online submission system: ScholarOne). The entire process of manuscript submission, peer-review, and resubmission to PHRP is done through the online system.

Manuscripts submitted to PHRP will be preliminarily reviewed by the Editorial Office. Manuscripts not conforming to the instructions will be returned to the corresponding authors without being considered for publication. Submitted manuscripts are also screened for possible plagiarism or duplicate publication using Crossref Similarity Check. If a paper that might be regarded as duplicate or redundant had already been published in another journal or submitted for publication, the author should notify the fact in advance at the time of submission.

Any inquiry concerning manuscript submission should be directed to the editorial office at ophrp@korea.kr.

Peer Review Process

This journal operates a double-blind review process. All contributions will be initially assessed by the editor for suitability for the journal. Papers deemed suitable are then typically sent to a minimum of 2 independent expert reviewers to assess the scientific quality of the paper. The Editor is responsible for the final decision regarding acceptance or rejection of articles. The Editor’s decision is final. The detailed review process is as follows.

• The Editorial Office of PHRP receives and reviews all submitted manuscripts, and all submitted manuscripts are considered confidential. The submitted manuscripts are initially screened for formatting. Once the manuscript is provisionally accepted, it is sent to the 2 most relevant referees for review.
• The referees are selected by the editor from the Editorial Board’s database or the board members’ recommendation. The referees are then requested to evaluate the manuscript based on originality, validity, presentation, and importance and interest, and, when considered necessary, statistics.
• Acceptance of a manuscript depends on the evaluation, critiques, and recommended decision made by the referees. A referee may recommend “accept,” “minor revision,” “major revision,” and “reject.” If there are conflicting decisions between referees, or between the author and referee(s),
the Editor-in-Chief has the full right to decide whether the manuscript will be published in the journal. Three repeated decisions of "major revisions" are equivalent to rejection, and rejected papers will not be considered further.

- The reviewed manuscript with comments, recommendations, and revisions is returned to the corresponding author. The corresponding author is to submit the revised manuscript accompanied by point-to-point replies to the comments given by the editor and how the revisions have been made. There should be a reasonable explanation for any noncompliance with the recommendations. In cases where references, tables, or figures are moved, added, or deleted during the revision process, renumbering must be done so that all references, tables, and figures are cited in numeric order. If the revised paper is not received within 2 months of decision, the manuscript is considered to have been withdrawn.
- When the final decision on the acceptance of the manuscript is made, the Editorial Office notifies the corresponding author. The peer-review process takes approximately 8–12 weeks.

MANUSCRIPT PREPARATION

General Requirements

- All manuscripts must be in grammatically correct English and should be created using MS Word. The manuscript must be double-spaced and written in an A4 page format. Do not leave a space between paragraphs. Only a single font (preferably Times New Roman) should be used in 11 point with margins of 2.5 cm.
- All numbers should be written in consecutive pages.
- All pages should be paginated consecutively.
- All numbers should be written in Arabic numerals throughout the manuscript except for the first word of the sentence. Texts should be justified on both sides and not hyphenated and headings should be in bold letters, aligned in the center. If possible, avoid using abbreviated words at the beginning of sentences.
- Abbreviations: Where a term/definition is repeatedly referred to (i.e., 3 times in the text), it is written in full when it first appears, followed by the subsequent abbreviation in parentheses (even if it was previously defined in the abstract); thereafter, the abbreviation is used.
- Gene nomenclature: Current standard international nomenclature for genes should be adhered to. Genes should be typed in italic font and include the accession number. For human genes, use the genetic notation and symbols approved by the HUGO Gene Nomenclature Committee (http://www.genenames.org/) or refer to PubMed (http://www.ncbi.nlm.nih.gov/sites/entrez).
- Units: Système International (SI) units must be used, with the exception of blood pressure values, which are to be reported in mmHg. Please use the metric system for expressions of length, area, mass, and volume. There should be a space between the numerals and the unit symbol. When indicating time, the 24-hour system is to be used.
- Math formulae: Present simple formulae in the line of normal text where possible and use the solidus (/) instead of a horizontal line for small fractional terms, e.g., X/Y. In principle, variables are to be presented in italics. Powers of e are often more conveniently denoted by "exp." Number consecutively any equations that have to be displayed separately from the text (if referred to explicitly in the text).

Reporting Guidelines for Specific Study Designs

For specific study designs, such as randomized control studies, studies of diagnostic accuracy, meta-analyses, observational studies, and non-randomized studies, authors are encouraged to consult the reporting guidelines relevant to their specific research design. A good source of reporting guidelines is the EQUATOR Network (https://www.equator-network.org/) and NLM (https://www.nlm.nih.gov/services/research_report_guide.html).

Manuscript Types

PHPR publishes editorials, original articles, review articles, guidelines, data profiles (including cohort profiles), special articles, short communications, viewpoints, editorials, commentaries, and correspondence, and book reviews.

- **Original articles** are papers containing results of basic and clinical investigations, which are sufficiently well documented to be acceptable to critical readers. These articles should be written in the following format: title page; abstract and keywords; main body (introduction, materials and methods, results, discussion, conclusion [if any]); references; and tables and figure legends. Manuscript limitations are 5,000 words, excluding the abstract, references, and tables and figure legends.
- **Review articles** provide concise reviews of subjects important to medical researchers, and can be written by an invited medical expert. These have the same format as original articles, but the details may be more flexible depending on the content. Manuscript limitations are 6,500 words from introduction to conclusion, 100 references, 10 figures and 10 tables. The abstract should
not exceed 200 words, and must be written as one unstructured paragraph.

- **Guidelines** are similar to original articles, but provide evidence-based recommendations expected to impact clinical research and practice. This category can include consensus-based statements of reporting standards or clinical practice guidelines.

- **Data Profiles (including Cohort Profiles)** present large data sets from specific populations that could be analyzed in epidemiological studies. Data Profiles should be structured with the following headings in the main text: Introduction, Collection, Data Resource Use, Strengths and Weaknesses, and Access. Cohort Profiles present up-to-date information about large population-based cohorts for which long-term data collection is planned. Data Profiles should be structured with the following headings in the main text: Introduction, Study Participants, Measurements, Key Findings, Strengths and Weaknesses, and Access. The main text of Data and Cohort Profiles is limited to 4,000 words, with an unstructured abstract of up to 200 words, a maximum of 7 tables and figures, and no more than 40 references.

- **Special Articles** deal with topics or issues that are relevant to public health, but without following a traditional study format. For example, articles in this category may address scientific methodology, wide-ranging ethical and social issues, scientific methodology, or other scholarly topics. Reports from consensus committees and working groups can be published as Special Articles. This category has a main text limit of 3,500 words, with an unstructured abstract of no more than 200 words, a maximum of 7 tables and figures, and no more than 40 references.

- **Brief reports** deal with issues of importance to biomedical researchers. The maximum length of the manuscript should be 2,000 words, including tables and figures.

- **Short communications** follow the general rules of the original article. The maximum length of the manuscript should be 3,000 words, including tables and figures.

- **Viewpoints** may deal with almost any topic deemed to be important in the fields of public health, ethics, health law, prevention, or health policy, and are not typically written in response to a specific article. Viewpoints should have a clear focus and present material in a well-organized and scholarly manner, but should not contain novel research findings or previously unpublished data. Although we welcome unsolicited viewpoint contributions, we request that authors contact the Editorial Office (ophrp@korea.kr) prior to submission to confirm that the proposed topic is suitable for the journal. The main text of Viewpoints is limited to 3,000 words, with an unstructured abstract of up to 150 words, a maximum of 4 tables and figures, and no more than 30 references.

- **Editorials** provide invited perspective on an area of PHRP, dealing with very active fields of research, current interests, fresh insights, and debates. An abstract is not required and a brief unstructured text should be prepared. Although editorials are normally invited or written by an editor, unsolicited editorials may be submitted. Manuscript limitations are 1,000 words and 20 references.

- **Commentaries** are brief articles with a narrow focus. The journal commissions most commentaries, but unsolicited commentaries will also be considered. Commentaries may undergo peer review. The length of commentaries should be limited to 1,000 words, 10 references, and 1 figure or small table.

- **Correspondence** is a comment from readers regarding a published article with a reply from the authors of the article. Manuscript limitations are 500 words, 2 tables/figures, and 5 references.

- **Book reviews** may be published. Please dispatch a book to the editorial office if you think the book is essential to public health personnel.

**Title Page**

Title page should include (1) the title of the article (less than 50 words); (2) name of the authors (first name, middle initial, last name in capitals) and institutional affiliation including the name of department(s) and institution(s) of each author; (3) name, full address (including the postal code) of the institutional affiliation, telephone and e-mail address of the corresponding author; (4) a running title of 50 characters or less including blank spaces; and (5) notes (disclaimers). Notes include ethics approval and consent to participate, conflict of interest, funding, availability of data, authors’ contributions, additional contributions, and ORCID of all authors. All contributors who do not meet the criteria for authorship as defined above should be listed in an additional contribution section. Examples of those who might be acknowledged include a person who provided purely technical help, writing assistance, or a department chair who provided only general support. Authors should disclose whether they had any writing assistance and identify the entity that paid for this assistance.

**Abstract and Keywords**

An abstract and 3–6 relevant keywords (in alphabetical order)
are required. Abstracts should be no more than 250 words in length. Abstracts should be structured, with the following section headings: Objectives, Methods, Results, Conclusion. For selecting keywords, refer to the MeSH browser (http://www.ncbi.nlm.nih.gov/mesh).

**Highlights**

All papers must include 3–5 short sentences presenting short summary or findings in the next of title page. The highlight section should be no more than 100 words, including spaces.

**Main Body**

- **Introduction** should provide concise yet sufficient background information about the study to provide the readers with a better understanding of the study, avoiding a detailed literature survey or a summary of the results.
- **Materials and methods** should contain detailed procedures of the study or experiment including investigation period, methods of subject selection, and information on subjects such as age, sex or gender, and other significant features, in order to enable the experiment to be repeated. A procedure that has been already published or standardized should be described only briefly using literature citations. Clinical trials or experiments involving laboratory animals or pathogens must elaborate on the animal care and use and experimental protocols, in addition to mentioning approval from the relevant committees. The sources of special equipment and chemicals must be stated with the name of the manufacturer. All statistical procedures used in the study and criteria for determining significance levels must be described. Ensure correct use of the terms "sex" (when reporting biological factors) and "gender" (identity, psychosocial or cultural factors). Unless inappropriate, report the sex and/or gender of study participants, the sex of animals or cells, and describe the methods used to determine sex or gender. If the study involved an exclusive population (only one sex, for example), authors should justify why, except in obvious cases (e.g., prostate cancer). Authors should define how they determined race or ethnicity, and justify its relevance. Institutional Review Board approval and informed consent procedures can be described as follows: The study protocol was approved by the Institutional Review Board of OOO (IRB No: OO-OO-OO). Informed consent was confirmed (or waived) by the IRB.
- **Results** should be presented in logical sequence. Only the most important observations should be emphasized or summarized, and the main or the most important findings should be mentioned first. Tables and figures must be numbered in the order they are cited in the text, kept to a minimum, and should not be repeated. Supplementary materials and other details can be separately presented in an appendix. The authors should state the statistical method used to analyze the results (statistical significance of differences) with the probability values given in parentheses.
  - **Discussion** should contain an interpretation and explanation of the results and important aspects of the study, followed by the conclusions drawn from them. Information already mentioned in the Introduction or Results sections should not be repeated and the main conclusions of the study may be presented in the discussion.
  - **Conclusion** (if any) must be linked with the purpose of the study stated in the abstract, and clearly supported by the data produced in the study. New hypotheses may be stated when warranted, but must be clearly labeled.

**References**

Authors are responsible for the accuracy and completeness of their references and for correct text citations.

- References are presented with [ ] following a surname in the main text, such as Kim [1] and Kim et al. [2]. When a reference is cited within the content, it is shown as [3] or [4,5] at the end. References should be searchable online.
- The last names and initials of all the authors (up to 3) should be included. For articles with more than 3 authors, list the first 3 authors only followed by "et al."
- References cited in tables or figure legends should be included in sequence at the point where the table or figure is first mentioned in the main text.
- Do not cite abstracts unless they are the only available reference to an important concept.
- Uncompleted work or work that has not yet been accepted for publication (i.e., an “unpublished observation” or “personal communication” should not be cited as a reference). In the references list, references should be limited to those cited in the text and listed in the order in which they appear in the text. The journals should be abbreviated according to the style used in the list of journals indexed in the NLM Journal Catalog (http://www.ncbi.nlm.nih.gov/nlmcatalog/journals).
- Use of DOI is highly encouraged. Note that missing data will be highlighted at the proof stage for the author to correct.
• Other types of references not described below should follow the ICMJE Recommendations (https://www.nlm.nih.gov/bsd/uniform_requirements.html).

Please refer to the following examples.

• Journal articles

• Books

• Websites

• Conference papers

• Dissertation

Each column should be appropriately headed with units in parentheses if numerical measures are given. All units of measurements and concentrations must be indicated. Footnotes are followed by the source notes, other general notes, abbreviation, notes on specific parts of the table (a), (b), (c), (d), and notes on level of probability (*, **, *** for p).

Figures should be numbered with Arabic numerals consecutively in figure legends. The figures must not be interfered and must be clearly seen. The legend for each light microscopic image should include name of the stain and magnification. Electron microscopic images should contain an internal scale marker. All figures may be altered in size by the editor. The legends should briefly describe the data shown, explain abbreviations or reference points, and identify all units, mathematical expressions, abscissas, ordinates, and symbols.

Figures that are drawn or photographed professionally should be sent as JPG or PPT files. However, if an article receives approval for publication, files must be submitted as .tiff or .pdf. Each figure must have a caption explaining the figure. The preferred size of the images is 8 × 8 cm but 16.5 cm in width × 8 cm in length is also acceptable. It is authors’ full responsibility to submit images of sufficient quality for accurate reproduction and to approve the final color galley proof. All images must be correctly exposed, sharply focused, and prepared in files of 500 dpi or more.

When tables and figures are mentioned together in the text, they should be presented in parentheses as follows: (Table 1; Figure 1), (Tables 1, 2; Figures 1−3).

Appendix and Supplemental Data

If any materials are not enough to be included in the main text such as questionnaires, they can be listed in the Appendix. Any supplementary materials that help the understanding of readers or contain too great an amount of data to be included in the main text may be placed as supplementary data. Not only a recording of the abstract, text, audio or video files, but also data files should be added here.

Tables and Figures

Tables should be simple, self-explanatory, and supplemental, and should not duplicate the text or figures. Each table must be on a separate page, not exceeding 1 page when printed, and have a concise and informative title. The tables should be numbered with Arabic numerals in consecutive order.

FINAL PREPARATION FOR PUBLICATION

Final Version

After the paper has been accepted for publication, the author(s) should submit the final version of the manuscript. The names and affiliations of the authors should be double-checked, and if the originally submitted image files were of poor resolution, higher-resolution image files should be submitted at this
Symbols (e.g., circles, triangles, squares), letters (e.g., words, abbreviations), and numbers should be large enough to be legible on reduction to the journal's column widths. All symbols must be defined in the figure caption. If references, tables, or figures are moved, added, or deleted during the revision process, renumber them to reflect such changes so that all tables, references, and figures are cited in numeric order.

**Manuscript Corrections**

Before publication, the manuscript editor will correct the manuscript such that it meets the standard publication format. The author(s) must respond within 48 hours when the manuscript editor contacts the corresponding author for revisions. If the response is delayed, the manuscript’s publication may be postponed to the next issue.

**Proofs and Reprints**

The author(s) will receive the final version of the manuscript as a PDF file. Upon receipt, the author(s) must notify the editorial office of any errors found in the file within 48 hours. Any errors found after this time are the responsibility of the author(s) and will have to be corrected as an erratum.

**Errata and Corrigenda**

To correct errors in published articles, the corresponding author should contact the journal’s editorial office with a detailed description of the proposed correction. Corrections that profoundly affect the interpretation or conclusions of the article will be reviewed by the editors. Corrections will be published as corrigenda (corrections of the author’s errors) or errata (corrections of the publisher’s errors) in a later issue of the journal.

**NOTICE:** These recently revised instructions for authors will be applied beginning with the February 2023 issue.
Author’s checklist

General Requirements

- The corresponding author (or the representative author of the co-corresponding authors) is the submitter of this manuscript.
- All manuscripts should be written in English.
- The main document with manuscript text and tables should be prepared in an MS Word (docx) or RTF file format.
- Manuscripts should be double-spaced in A4-size pages.
- Manuscripts should include line numbers.
- All pages should be numbered consecutively, starting with the abstract.

Title Page

- The title page and the rest of the manuscript text are prepared separately in two files (not combined together).
- The title page is arranged in the following order: article title, authors’ full name(s), affiliation(s), and corresponding author’s information, running title (less than 50 characters), notes.
- The notes section including (1) ethics approval and consent to participate, (2) conflicts of interest, (3) funding, (4) availability of data, (5) author contributions, (6) additional contributions, and ORCID is in title page, not in the manuscript.

Abstract

- The abstract does not exceed 250 words (Objectives, Methods, Results, Conclusion) for original articles and 200 words for reviews. Up to 3–6 keywords are listed at the bottom of the abstract.

Main Text

- The manuscript is organized according to following sequence: Title page, Abstract and keywords, Main text, References, Tables, and Figure legends.

Tables and Figures

- All tables and figures are numbered in the order of their appearance in a main text.
- Tables are included at the end of the manuscript as editable text and not as images.
- Figures are as separate files, in jpg, ppt, tiff, or pdf format.

References

- References are listed in proper format.
- All references listed in the reference section are cited in the text and vice versa.
Copyright Transfer and Conflict of Interest Disclosure Form

Title of the paper: ____________________________________________________________

I. Copyright Transfer Form

The authors hereby transfer all copyrights in and to the manuscript named above in all forms and media, now or hereafter known, to the Korea Disease Control and Prevention Agency effective if and when the paper is accepted for publication in the *Osong Public Health and Research Perspectives*. The authors reserve all proprietary right other than copyright, such as patent rights. Everyone who is listed as an author in this article should have made a substantial, direct, intellectual contribution to the work and should take public responsibility for it. This paper contains works that have not previously published or not under consideration for publication in other journals.

II. Conflict of Interest Disclosure Form

All authors are responsible for recognizing any conflict of interest that could bias their work in the acknowledgments, disclosing all financial support and any other personal connections.

Please check the appropriate box below:

☐ No author of this paper has a conflict of interest, including specific financial interests, relationships, and/or affiliations relevant to the subject matter or materials included in this manuscript.

OR

☐ The authors certify that all conflicts of interest, as applicable to each author, including specific financial interests, relationships, and/or affiliations relevant to the subject matter or materials are disclosed in the manuscript.

(Please describe in detail about these interests.)

__________________________________________________________

These interests may include one or more of the following: employment; consultancy within the past two years; ownership interests – including stock options – in a start-up company, the stock of which is not publicly traded; ownership interest - including stock options but excluding indirect investments through mutual funds and the like - in a publicly traded company; research funding; honoraria directly received from an entity; paid expert testimony within the past two years; any other financial relationship (e.g., receiving royalties); membership on another entity’s Board of Directors or its advisory committees (whether for profit or not for profit).

☐ All authors certify that the work followed the research ethics and have approved the submission of the manuscript for publication.
